Reverse the operations to assemble and, after pressing on the pinion flange, slip on the washer and nut. Tighten the nut until the bearings have a preload drag of 24 to 32 inch pounds on new bearings or 10 to 15 inch pounds on used bearings to rotate the pinion shaft.

To adjust the preload, draw up the nut until the spacer starts to buckle. Check the pull as shown in Figs. 2 or 3, depending upon the equipment available. This adjustment must be made every time the flange nut is removed or loosened. If the adjustment is to be made with the differential unit in the carrier, the rear wheels must be jacked off the floor.

The pinion can be moved in toward the center of the axle by removing the required thickness of shims from between the spacer and the carrier. If it is to be moved away from the center of the axle, add shims.

Note — A new spacer is required between the pinion bearings when a new ring gear and pinion set is installed, either outer or inner members of either pinion bearing is changed, a new carrier casting used, or pinion adjusting shim thickness is increased. When the same pinion flange is removed and reinstalled as when an oil seal is replaced, checking for pinion bearing preload with a torque wrench is not necessary if care is taken to tighten the nut to exactly its previous position. Should a new pinion flange be required, a torque wrench reading should be taken before loosening the nut and the nut tightened to the same torque wrench reading.

Fig. 3 Measuring pinion bearing preload with a spring scale

The side bearing adjustment of the pedestal cap spread must be determined. With the differential case assembled in the carrier, adjusting nuts in place, and pedestal caps tightened just snug, proceed as follows:

1. Back off the right adjusting nut (one opposite ring gear) four turns.
2. Tighten the left hand adjusting nut against the bearing race, removing all lash between the ring gear and pinion. Then back off four notches, leaving slot in adjusting nut in line with lock cap screw hole in bearing cap.
3. Tighten right hand adjusting nut, watching race of bearing. When bearing race starts to turn, continue to tighten two to three notches, align slot in nut
4. Tighten cap bolts 70 to 75 lbs. ft. with hole in bearing cap.
5. Clamp an indicator to differential carrier and check backlash. This should not be less than .004″ nor more than .008″.
6. If necessary, adjust by turning the nuts in the required direction to obtain the correct lash; always moving both nuts an equal number of notches.
7. Again tighten pedestal caps 70 to 75 lbs. ft. and check lash. After the correct backlash has been obtained, proceed as follows:
8. With the special gauge postioned as shown in Fig. 4, check the clearance between the gauge and the machined surface of the pedestal cap—which should be .005″. If the clearance is incorrect, loosen the right hand bearing cap bolts and adjust the nut as required (one notch at a time) to obtain .005″ clearance. Be sure bearing cap bolts are tight each time clearance is checked. Do not tighten adjusting nut more than 4 notches nor less than 2 notches.
9. Recheck backlash. If necessary, move adjusting nuts an equal number of notches to obtain. 004″ to .008″ backlash.

Note — On eight-cylinder models, the differential carrier is a press fit in the axle housing. When installing the carrier it must be held so the pedestal caps are in line with the supports in the housing before the assembly can be drawn into the axle housing.

To perform this operation, position the gasket and install 3 special pilot studs into the housing as shown in Fig. 5. Assemble the carrier over the pilot studs. Then temporarily use four 1½″ long bolts, two each side as shown, and tighten the bolts evenly to draw the carrier into the housing. Remove the pilot studs and install 6 of the regular carrier bolts in the vacant holes. Remove the four temporary bolts, install the regular ones and tighten all 40 to 45 lbs. ft.

1957-62 REAR AXLE

The differential carrier is larger and heavier than previous models to withstand the increased engine torque without excessive deflecting or twisting, Fig. 6. The number of splines have been increased on side gears, axle shafts and

Fig. 4 Adjusting differential carrier pedestal spread

drive pinion. The drive pinion and ring gear, pinion bearings, side bearings, side gears and differential case are larger. The pinion adjusting shims are located between the pinion head and the inner bearing race instead of in front of the outer bearing race on 1956. The differential pinion cross shaft is locked in the case by means of a screw and washer instead of a roll pin used in 1956. The carrier attaching screws are pressed into the axel housing and the carrier is attached to the housing screws by means of nuts and lockwashers.

Service Procedures

All service procedures are the same as in 1956. Due to the new construction, however, a new set of pinion adjusting shims is required. Shims are available in thicknesses of .004″, .005″ .006″, .007″ and .010″. The pinion rear bearing must be removed from the pinion to change the shim pack. The thickness of the shim pack must be established by the red (or white) lead test as outlined in the *Rear Axles* chapter.

Fig. 5 Installing machined carrier into axle housing

Fig. 6 Rear axle, 1957-62

AXLE SHAFT

These axle shafts are supplied with the wheel studs pressed into the flange. Studs on the left-hand axle have left-hand threads.

To remove a shaft, unfasten the brake drum from the flange and the brake support plate from the axle housing. Pull the bearing retainer plate away from the brake plate, using care not to dislodge the brake plate as the brake line might be damaged. Remove the shaft with a puller.

POWER BRAKE UNIT, REPLACE

1960-62

1. Disconnect hydraulic line. Plug or tape line to prevent dirt from entering hydraulic system.
2. Disconnect vacuum lines from vacuum cylinder.
3. Disconnect operating rod from brake pedal.
4. Unfasten vacuum cylinder from cowl (4 nuts).
5. Reverse sequence of operations to install and torque attaching nuts 8-16 ft. lbs.

1959

1. Disconnect hydraulic line. Plug line with rubber stopper to prevent dirt entering the hydraulic system.
2. Disconnect wires from stop light switch.
3. Remove brake pedal and bracket.
4. Slide steering column grommet and retainer up mast jacket.
5. Remove floor cover plate screws.
6. Remove cover plate-to-power cylinder bolt and remove cover plate.
7. Disconnect vacuum hose and remove power brake unit through toe pan opening.
8. Reverse removal operations to install.
9. Fill master cylinder and bleed system.

1956-58

1. Disconnect positive battery cable at junction block on right fender filler plate. Disconnect solenoid lead wire (purple) from wiring harness, then pull cable through sleeve on power brake.
2. Disconnect brake line at junction block at frame. Use care to prevent dirt from entering the hydraulic line. Plug brake line with a rubber stopper.
3. Disconnect wires from stop light switch and fold back floor mat.
4. Remove three brake pedal attaching bolts and remove bracket and pedal assembly.
5. Remove mast jacket grommet and retainer clamp and slide grommet and retainer up mast jacket.
6. Remove floor cover attaching screws.
7. Remove speedometer cable from clips.
8. Remove two cover plate-to-power cylinder bolts and remove cover plate while positioning power brake unit so it rests on edge of opening in toe pan.
9. Disconnect vacuum hose and remove power brake unit through toe pan opening. *When reinstalling hose, position clamp so screw head may be reached from below car.*
10. Reverse foregoing procedure to install, fill master cylinder and bleed system.

1955

1. Disconnect the hydraulic line at the power brake master cylinder.
2. Disconnect vacuum hoses at power cylinder, and remove dipstick.
3. Disconnect leads from stop light switch and fold back floor mat.
4. Remove three bolts and take off brake pedal and bracket assembly.
5. Slide mast jacket grommet up on mast jacket.
6. Remove mast jacket cover plate and power cylinder assembly.
7. Remove cover plate from power cylinder.
8. Install in the reverse order, fill master cylinder with brake fluid and bleed system.

BRAKE MASTER CYLINDER, REPLACE

1960-62

The standard brake master cylinder can be removed without disconnecting the push rod and clevis. The master cylinder on cars with power brakes can be removed without removing the vacuum cylinder from the car. Power cylinders can be identified by the bronze Moraine cylinder and the black Bendix cylinder.

1. Disconnect hydraulic line at master cylinder and plug or tape end to prevent dirt entering the system.
2. If equipped with standard transmission, install a gauge pin in the holes provided in the frame side rail and "X" member to hold clutch linkage in position; then disconnect clutch linkage from clutch pedal bellcrank and remove bellcrank.
3. Remove master cylinder (4 nuts). On Moraine units, remove and record number of any shims found between master and power cylinders. *On Moraine units, the master cylinder piston will remain attached to the vacuum unit. If piston is to be serviced, the vacuum unit must be removed and disassembled.*

1959

1. Disconnect junction block-to-master cylinder hydraulic line at master cylinder. Plug line with rubber stopper.
2. Unfasten and remove master cylinder (with boot) from dash panel. Push rod and clevis need not be removed.
3. Install in reverse order of removal and bleed hydraulic system as outlined in the *Hydraulic Brake System* chapter.

1953-58

To remove the master cylinder, disconnect the push rod from the brake pedal. Disconnect the brake pipe from the master cylinder and tape its end to prevent dirt from entering. Unfasten the cylinder from the frame bracket and remove it from the car.

Install in the reverse order and bleed the hydraulic system as directed in the *Hydraulic Brake* chapter.

Front End and Steering Section

CAMBER & CASTER

1961-62, Fig. 1

Camber and caster are adjusted by shims placed between the upper pivot shafts and the frame. In order to remove or install shims, *do not remove weight from front wheels.* Loosen pivot shaft-to-frame bolts. To gain access to these bolts, loosen top and rear fasteners on fender filler plate aprons.

To decrease positive caster, add shim at the front bolt. To increase positive caster, remove shim at the front bolt.

To increase camber, remove shims at both front and rear bolt. To decrease camber, add shims at both bolts.

By adding or subtracting an equal amount of shims from both front and rear bolts, camber will change without affecting caster adjustment. When changing shims, refer to the following chart:

Shim Thickness	Camber Change	Caster Change
.020	⅛°	⅜°
.060	⅜°	1⅛°
.120	¾°	2¼°

1957-60, Fig. 1

Camber and caster are adjusted by shims placed between the upper pivot shafts and the frame. In order to remove or install shims, raise the car to remove weight from the front wheels, then loosen the pivot shaft-to-frame bolts.

To *decrease* positive caster, *remove* shim at front bolt. To *increase* positive caster, *add* shim at front bolt.

To *increase* camber, *add* shims at both the front and rear bolts. To *decrease* camber, *remove* shims at both the front and rear bolts.

By adding or subtracting an equal amount of shims from both the front and rear bolts, camber will change without affecting caster adjustment. Refer to shim chart when changing shims as follows:

Shim Thickness	Camber Change	Caster Change
.020″	⅛°	⅜°
.060″	⅜°	1⅜°
.120″	¾°	2¼°

1955-56

Caster—Loosen the clamp bolt at the upper end of the steering knuckle support. Turn the eccentric bushing to obtain desired adjustment. Turning the bushing in a clockwise direction will increase caster; turning it counterclockwise decreases caster.

Camber—Since the camber adjustment is controlled by the eccentric action of the bushing, ½ turn of the bushing gives the maximum adjustment and is all that should be required. Moreover, changing camber will change caster angle slightly but it will usually be within proper limits.

TOE-IN, ADJUST

To adjust the toe-in, loosen the clamps at both ends of the adjustable tubes at each tie rod. Then turn the tubes an equal amount until the toein is correct. Turning the tubes in the direction the wheels revolve when the car moves forward decreases the toe-in and vice-versa. When the adjustment is complete, tighten all clamp screws.

WHEEL BEARINGS, ADJUST

Tighten the spindle nut with a torque wrench to approximately 17 lb. ft. to insure that all parts are properly seated and threads are free. Back off nut and retighten to 4 lb. ft. If cotter pin hole in spindle and slot in nut line up, insert cotter pin; if not, back off spindle nut to the nearest line-up of slot and hole and insert cotter pin.

When installing front wheel hub and drum, the complete inner bearing, including the cone, should always be assembled to the hub, and the assembly then installed on the spindle.

Fig. 1 Upper control arm mounting showing location of caster and camber shims. 1957-62

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure the front wheel bearings are properly adjusted and that the control arms are tight. Then check ball joints for wear as follows:

To check lower ball joint, jack up under the frame front torque box on each side. Set up a dial indicator at the lower vertical edge of the wheel. Then with one hand at the top and the other at the bottom of the tire, rock the wheel at top and bottom. If more than 1/16″ movement is evident on the dial gauge, the lower ball joint should be replaced.

To check upper ball joint, disconnect it from the steering knuckle. Install nut on ball stud and, using an inch pound torque wrench, rotate the stud in a clockwise direction. The reading should be 10 to 60 inch lbs. If not within these limits, upper ball joint should be replaced.

1957-62 FRONT END REPAIRS

This suspension, Fig. 2, utilizes ball joints instead of knuckle supports, kingpins and thrust bearings.

Shock Absorber, Replace

Remove the pivot bolt from the upper end of the shock absorber. Unfasten the shock absorber from the lower control arm and remove the unit out through the lower control arm spring seat.

To install the shock absorber, reverse

the sequence of removal. Torque the pivot bolt 60-70 lb. ft. and the cap screws 15-25 lb. ft.

Stabilizer, Replace

Disconnect each side of stabilizer linkage by removing nut from top of link bolt. Pull out bolt from bottom of linkage and remove retainers, grommets and spacer. Unfasten stabilizer bracket from frame and remove bar, rubber bushings and brackets.

To install, reverse sequence of removal operations. The rubber bushings should be positioned squarely in the brackets. Torque stabilizer link nut 8-18 lb. ft. and bracket bolts 25-35 lb. ft.

NOTE—Never lubricate stabilizer bar rubber bushings as they are dependent upon a bonding of the rubber to the bar for proper stabilizing action.

Upper Control Arm and Ball Joint, Replace

NOTE—The ball joint is riveted to the control arm and should not be removed from it. If necessary to replace either part, they should be replaced as an assembly. To remove the upper control arm, proceed as follows:

1. Raise front of car and place jack stands under lower control arm.
2. Remove nut from ball joint.
3. Strike the steering knuckle with a hammer in the area of the ball joint stud to loosen the joint.
4. Support hub and drum to prevent their weight from damaging brake hose.
5. If necessary to remove pivot shaft from control arm, loosen pivot shaft bushings at this time.
6. Unfasten pivot shaft from frame, being sure to locate wheel alignment shims so they can be reinstalled in their original location during reassembly.
7. Remove control arm and pivot shaft from car.

Lower Control Arm, Ball Joint and/or Spring, Replace

NOTE—The ball joint is riveted to the control arm and should not be removed from it. If either part is to be replaced, both should be replaced as an assembly.

1. Raise and support from of car with stand jacks.
2. Remove wheel assembly.
3. Disconnect stabilizer link from lower control arm.
4. Remove shock absorber.
5. Place jack under control arm to be removed.
6. Remove nut from lower ball joint.
7. Strike steering arm with a hammer in the area of the ball joint stud to break the joint loose.
8. Slowly lower hydraulic jack until spring is fully extended and remove spring. *Important*—Left and right springs are not interchangeable. Spring part number is stamped on outer side of end coil.
9. If necessary to remove lower control arm, unfasten pivot shaft from frame crossmember.

Fig. 2 Front suspension. 1957-62

1955-56 FRONT END REPAIRS

NOTE—Except for the new type shock absorber which necessitates the use of a new upper control arm, service on the front suspension is the same as for previous models. Therefore, follow the procedure given for *Front Wheel Bearings* and *Kingpins and Bushings*. Service on the *Front Spring* and *Lower Control Arm* is also the same except that the shock absorber must be removed—the procedure for which is given below.

Shock Absorber, Replace

1. To remove a shock absorber, hold the shock absorber mounting stem with a wrench while removing the pal-nut and retaining nut. Then remove retainer and rubber grommet.
2. Remove bolts and lockwashers attaching lower mounting brackets to the spring seats on the lower control arm and pull the shock absorber and bracket down through the opening in the spring seat.
3. Clamp lower mounting bracket in a vise and remove the pivot bolt and nut, rubber grommet and spacer.
4. Inspect all grommets and replace if not in good condition. If shock absorber operation is faulty, it should be replaced as it cannot be repaired.
5. Reverse the foregoing procedure to install the shock absorber, being certain that the unit being installed is correct for the car model as indicated by the code and part number stamped on the outer tube.

Upper Control Arm

If the control arm is bent or broken, use a new arm assembly which includes the shaft, bushings and dirt seals. If only the shaft and bushings require replacement, proceed as follows:

1. Remove generator and engine front mounting nuts and raise the engine just enough to allow removal of the upper arm shaft bolts.
2. Remove pivot pin and bushings and shaft attaching bolts and remove the arm assembly from the car.
3. Unscrew the shaft bushings and remove shaft and seals from upper arm.
4. Before installing any new parts, check the distance between the inner ends of the upper arm.
5. Install rubber seal over each end of upper arm shaft, with the large (or bell) end of seals outward.
6. Insert one end of shaft with the seal in one end of the upper arm and force the opposite end of the shaft into the other end of the arm.
7. Fasten the upper arm securely in a vise (close to one end to avoid springing or distortion).
8. Apply a liberal amount of white lead or Lubriplate to both bushings before installation.
9. Start the first bushing on the shaft and into the upper arm at the same time. Turn the bushing until the head is tight against the arm. Then tighten to a minimum of 100 lbs. ft. torque.
10. Center the shaft between the ends of the arm and install the second bushing in the same manner, turning the shaft as required to thread into the bushing so that no binding exists.
11. Before installing the upper arm and shaft assembly, turn the shaft to locate the bolt holes equally distant from ends of arm and bolt the shaft securely to the frame crossmember.
12. Lower engine and tighten front mounting nuts. Reinstall generator.
13. Reinstall upper pivot pin, bushings and seals. Then check front wheel alignment.

HORN SOUNDER & STEERING WHEEL

1959-62

1. Disconnect horn wire from wiring harness.

2. On Standard wheel, remove cap-to-steering wheel attaching screw, pull cap from wheel, then disconnect horn switch wire from contact lead.
3. On Deluxe wheel, pry cap and emblem from shroud.
4. Remove wheel nut and use a puller to remove wheel.
5. To install, reverse above procedure, being sure to align marks on steering wheel hub and shaft. Torque nut to 25 ft. lbs. and stake it to steering shaft.

1958

1. Disconnect horn wire.
2. Remove cap by inserting a sharp tool under its edge and prying upward.
3. Remove steering wheel nut and use puller to remove wheel.
4. When installing wheel, be sure to align mark on wheel hub with mark on steering shaft.

1957

1. Disconnect horn wire.
2. On Standard wheel, insert a sharp tool under edge of cap and pry upward.
3. The Deluxe horn ring cap is retained to the horn ring hub by a screw which is accessible from underside of cap.
4. Remove wheel nut and use a puller to remove wheel.
5. When installing wheel, be sure to align mark on wheel hub with mark on steering shaft.

1955-56

The horn button on Standard wheel is held in place by means of dimples on horn button retainer cup. The horn button may be removed by inserting a sharp tool under edge of button and prying upward. Removal of steering wheel nut will permit removal of horn contact assembly. Use puller to remove wheel.

The Deluxe horn button is held in place by two clips on ends of horn button which engage horn ring hub. They are accessible from underside of wheel. To remove horn button, use a small screwdriver to relieve spring tension on one end and lift button from its seat. The steering wheel nut will have to be removed in order to remove horn contact plate, horn ring or steering wheel.

STEERING GEAR, REPLACE

1955-62 Standard Gear

1. Remove steering wheel, upper bearing spring and seat.
2. Turn back floor mat and remove mast jacket cover plate attaching screws. *On 1960-62 models, disconnect horn wire and turn signal wire, and neutral safety switch and back-up light wires on cars with Hydra-Matic from switches on mast jacket and horn wire connector.*
3. On 1957-62, remove upper mast jacket clamps, and disconnect shift linkage from lower end of mast jacket.
4. On 1955-56, loosen upper and lower mast jacket clamps. Hoist car and remove engine filler plate.
5. Remove pitman arm from pitman shaft.
6. Unfasten steering gear from frame.
7. On 1955-56, remove gear by pulling it down out of mast jacket.
8. On 1957-60, remove gear and mast jacket assembly by pulling it up through opening in floor. Loosen lower clamp and remove mast jacket from gear.
9. On 1961-62, remove gear by pulling it out from under car.
10. To install, reverse foregoing procedure. Tighten upper mast jacket clamp before tightening steering gear frame.

MANUAL STEERING GEAR REPAIRS

Disassemble, Figs. 3, 4

1. Loosen adjusting screw lock nut and remove housing side cover by unscrewing adjusting screw.
2. Loosen lock nut and back off worm bearing adjuster several turns, then remove housing end cover and gasket.
3. Remove lower thrust bearing, steering shaft and upper bearing from housing.
4. Remove ball return guide clamps and guides from ball nut, turn ball nut over to remove balls and remove ball nut from steering shaft worm.

Inspection of Parts

1. Clean and inspect all ball and roller bearings and races, including race in housing.
2. Inspect pitman shaft bushings in gear housing and end cover. Replace bushings in housing and replace end cover if bushings are worn excessively.
3. It is advisable to replace pitman shaft grease seal in housing to avoid possible leakage of lubricant. Seal must be installed with feather edge toward inside of housing.
4. Inspect steering shaft for wear or pits in bearing races, which would require replacement of shafts.
5. Check shaft for straightness.
6. Inspect teeth of ball nut and pitman shaft. If scored or excessively worn it is advisable to replace both parts to insure proper mating of teeth.
7. Check serrations of pitman shaft; if twisted, replace shaft.
8. Check fit of pitman shaft adjusting screw and shim in slot in end of pitman shaft. *With shim in place, screw head must be free to turn in slot with zero to .002" end play.* If end play is excessive, selectively fit a new shim, which are furnished in four different thicknesses.
9. Inspect steering column jacket for distortion. A ripple or wavy feeling of jacket surface, particularly at lower end, will usually indicate a sprung jacket. Replace jacket if sprung or otherwise damaged.
10. Inspect control shaft bearing in tube of gear housing, and steering shaft upper bearing in control lever housing support. Replace worn or damaged parts.

Assemble

To assemble the steering gear, reverse the order of procedure given for disassembly. In addition, observe the following instructions.

1. Lubricate bearings and gears with steering gear lubricant.
2. Use all new gaskets to avoid oil leaks.
3. When assembling ball nut on worm, be sure to place 30 balls in each circuit, making a total of 60 balls.
4. When installing pitman shaft, avoid damaging or turning the feather edge of leather seal in gear housing.

Fig. 3 Exploded view of manual steering gear

5. Temporarily install steering wheel and adjust worm shaft thrust bearing for proper load and pitman shaft for proper gear lash as described below.

Adjustments

1. Disconnect steering linkage from pitman arm.
2. Turn steering wheel gently in one direction until it stops, then turn it back one revolution. *Never turn steering gear hard against stopping point as damage to ball nut assembly may result.*
3. Check lash between ball nut and pitman shaft by working pitman arm. If a perceptible lash *does not* exist, loosen lock nut and turn pitman shaft adjusting screw counterclockwise until lash can be felt when working pitman arm.
4. Turn steering wheel slowly from one extreme to the other. Wheel should turn freely and smoothly through entire range. Roughness indicates faulty worm thrust bearings or pitted races. Hard pull or binding indicates misalignment of steering gear in its mountings, or an excessively tight adjustment of worm thrust bearings. Any misalignment must be corrected before steering gear can be properly adjusted.
5. Tighten housing and cover bolts.
6. Loosen worm thrust bearing adjuster lock nut and turn thrust bearing adjuster until a slight load is felt when turning steering wheel near extreme end positions, then tighten lock nut. (1956 gears have an external hex which replaces slot on bearing adjuster used formerly). *Do not back out adjuster far enough to* permit thrust bearings to get out of line with ends of worm.
7. After locking bearing adjuster, check load on thrust bearings with steering wheel turned to near one extreme position.
8. Attach a spring scale to rim of steering wheel. The pull required to keep steering wheel turning slowly should be between ½ and ⅞ lbs. Readjust to obtain this load if necessary.
9. Turn steering wheel from one extreme to the other while counting the turns. Then turn wheel back exactly one-half the total number of turns and have the lower spoke pointing straight down. This places the steering gear on the "high point" at which no lash should exist between ball nut and pitman shaft teeth.
10. Tighten housing side cover bolts. Loosen lock nut and turn pitman shaft adjusting screw clockwise until lash is just removed.
11. After "tightening" adjusting screw lock nut, rotate wheel back and forth to check for tight spots. Also recheck pull at wheel rim as given above.
12. The pull required to keep the wheel moving through the "high point" should be between 1½ to 2 lbs. Readjust if necessary to remove tight spots.

Fig. 4 Manual steering gear adjustments

POWER STEERING UNIT, REPLACE

Removal, 1955

The following procedure leaves the mast jacket in the car, thereby eliminating the possibility of scratching the finish on the jacket. It also eliminates disconnecting the shifter linkage and the wiring housed in the mast jacket.

1. Disconnect battery.
2. Drain fluid reservoir on hydraulic steering pump.
3. Disconnect hydraulic hoses at gear and pump. *Use plastic plugs or tape to cover openings against dirt entering.*
4. Loosen mast jacket-to-steering gear housing clamp.
5. Remove steering wheel.
6. Mask the steering column for about 2 in. above the instrument panel bracket.
7. Loosen the steering column in the bracket.
8. Remove floor mat and floor pan plate attaching screws.
9. Pull mast jacket up. *The upward travel will be limited by the shifter linkage striking lower side of toe pan.*
10. Place a 2 in. block between left front shock absorber arm and frame.
11. Jack up front end of car at least 10 in. and place car stand under frame.
12. Remove left side filler plate, and pitman arm from shaft.
13. Remove starting motor and wire guide bracket.
14. Remove three steering gear-to-frame bolts.
15. Remove gear by pulling it down out of mast jacket. *Carefully turn gear as it is removed so that all fittings and pipes will clear the frame and lower control arms.*

Installation Notes

After installing the steering wheel, locate the mast jacket to provide ⅛ to $\frac{3}{16}$ in. clearance between the steering wheel and collar.

After tightening the steering column-to-dash bracket clamp screws, install the floor pan filler plate and floor mat and then tighten the three steering gear housing-to-frame bolts. *It is important that this is done at this time as correct alignment is essential for free axial movement of the steering shaft.*

After the installation is completed, fill the fluid reservoir and bleed the lines as outlined in the *Power Steering* chapter.

Removal, 1956-62

1. Scribe marks on coupling flange and steering shaft flange.
2. Disconnect hoses from pump and cap pump and hose fittings.
3. Hoist car and on 1956-58 remove engine filler plate. Remove pitman arm from pitman shaft.
4. Separate coupling from coupling flange.
5. Unfasten steering gear from frame and remove gear with hoses attached.

Installation Notes

When installing the gear assembly, align the coupling flange and steering shaft flange alignment marks so that the steering wheel will be positioned properly. Make sure that gear housing alignment pin enters hole in frame before tightening mounting bolts.

Bleeding System

After gear is installed and hoses connected to pump, add Hydra-Matic Fluid to the reservoir to the Full mark. With engine running, loosen bleed screw in pitman shaft side cover, turn steering wheel through its full travel 2 or 3 times to bleed all air from the system, and tighten bleed screw. Recheck oil level and add if necessary.

Speedometer, Radio & Windshield Wiper

SPEEDOMETER REMOVAL

1962

1. Disconnect printed circuit connector.
2. Disconnect speedometer cable.
3. Remove 3 cluster-to-instrument panel screws.
4. Remove cluster from front of panel.

1961

1. Disconnect parking brake from instrument panel and loosen it at cowl. Disconnect left-hand instrument panel brace, headlamp switch and

ventilation or air conditioning control assembly from panel.
2. Remove light sockets, wiring harness and safety sentinel buzzer from speedometer.
3. Remove two speedometer mounting nuts and rotate assembly downward, *being careful not to damage printed circuit.*
4. Disconnect speedometer cable and withdraw assembly from left side of steering column from under instrument panel.

1960

To remove the speedometer or any other instrument, the instrument cluster must be removed. The procedure is as follows:
1. Remove air conditioning, heater or ventilation controls if car is so equipped.
2. Remove two instrument panel-to-cowl braces.
3. Remove headlamp switch and ignition switch from instrument panel.
4. Disconnect wiring harness, clock, safety sentinal and speedometer cable at cluster.
5. Remove cluster-to-instrument panel attaching nuts; then remove cluster from rear of instrument panel and out to left of steering column.

1959

To remove the speedometer or any other instrument, the instrument cluster must be removed. The procedure is as follows:
1. Remove the two left hand instrument panel molding-to-instrument cluster bracket nuts.
2. Remove air conditioning, heater or ventilation controls if car is so equipped.
3. Remove two instrument panel-to-cowl braces.
4. Disconnect wiring harness and speedometer cable from cluster.
5. Remove cluster-to-instrument panel attaching nuts and remove cluster from rear of panel.
6. Remove speedometer from cluster.

1957-58

To remove the speedometer or any other instrument the instrument cluster must be removed. The procedure is as follows:
1. Remove right-hand instrument panel molding screw and position molding away from cluster. Windshield wiper cables and hoses *do not* have to be disconnected.
2. Remove headlamp switch, parking brake light, ignition-starter switch and cigar lighter.
3. Remove air conditioning, heater or ventilation controls if so equipped.
4. Remove radio knobs and panel.
5. Remove upper clamp from steering column bracket.
6. Remove H-M indicator needle.
7. Remove lower clamp from steering column bracket. On manual steering equipped cars, loosen gear-to-frame bolts. Pull mast jacket away from bracket.
8. Remove steering column bracket from instrument panel.
9. Disconnect wiring harness and speedometer cable from cluster.
10. Remove cluster-to-instrument panel nuts; then remove cluster from front of dash.
11. The speedometer, or any other instrument, may now be removed from cluster.

1956

All the instruments except the speedometer can be removed from the back of the cluster without removing the cluster assembly. To remove the speedometer, first remove the cluster assembly as follows:
1. Disconnect battery and all electrical connections and lights from cluster.
2. Disconnect speedometer cable.
3. Remove H-M indicator needle.
4. Remove cluster-to-adapter nuts and pull cluster free from adapter studs.
5. Guide cluster through opening in center molding.

1955

The speedometer may be removed from the instrument cluster without removing the cluster from the instrument panel.

RADIO REMOVAL

1962

1. Disconnect radio lead from wiring harness.
2. Disconnect front and rear seat speakers.
3. Disconnect antenna lead-in from radio (through opening in top of glove box).
4. On Super Deluxe radios, disconnect foot selector plug-in connector from right side of radio.
5. Remove or disconnect any accessory switches or dummy plates from instrument panel (above radio escutcheon).
6. Disconnect bracket from radio side support and radio-to-instrument panel attaching nuts. Then remove radio from front of panel. If dial light is to be removed, remove radio top cover.

1960-61

1. Remove glove box on 1960.
2. Disconnect radio lead from wiring harness.
3. Disconnect rear seat speaker lead (if equipped).
4. Disconnect antenna lead-in from radio. On 1961, access is through opening in top of glove box.
5. On Super Deluxe models, disconnect foot selector plug-in connector from right side of radio.
6. Remove control knobs and nuts from front of instrument panel.
7. Disconnect bracket from radio side support while supporting radio to prevent it from falling.
8. Remove radio.

1959

To remove the Deluxe, Super Deluxe or Transportable radio, proceed as follows:
1. Remove glove box.
2. Disconnect radio lead from wiring harness.
3. On cars equipped with rear seat speaker, disconnect speaker lead.
4. Disconnect antenna lead-in from radio.
5. On Super Deluxe models, disconnect foot selector plug-in connector from right side of radio.
6. On Transportable models, remove radio. Remove rack from bottom of push button unit and let rack rest on bottom flange of glove box opening.
7. Remove radio panel nuts from rear of instrument panel.
8. Disconnect radio from side supports while supporting radio to prevent it from falling. Remove radio.
9. On Transportables, feed rack unit through radio opening as dictated by wire attachments.

1958 Transportable

Open glove box door. Unlock padlock from lock release and remove. Pull down handle on face of radio. Push down on lock release and remove radio.

1957-58 Standard Radio

Remove speaker and glove box. Disconnect radio lead (green) from wiring harness and antenna lead from radio. Remove knobs, nuts and washers from control shafts. Disconnect radio from side supports and remove.

WINDSHIELD WIPER

1960

1. To remove wiper motor, first make sure motor is in parked position.
2. Remove cowl vent grille.
3. Disconnect electrical connectors from motor.
4. Remove windshield washer hoses (if equipped).
5. Remove retainer (2 speed) or nut (1 speed) securing drive linkage to motor and disengage drive linkages from motor. *Hold crank arm on single speed motor with a wrench when removing or tightening linkage-to-crank nut.*
6. Unfasten motor and lower motor from cowl.
7. Reverse procedure to install. *The linkage for right transmission overlaps linkage for left transmission. Apply medium bodied sealer to motor attaching screws.*

1961-62

1. To remove wiper motor, first make certain motor is in parked position.
2. Remove cowl vent grille.
3. Remove screw securing ground strap to cowl, and disconnect electrical connectors from motor. Remove windshield washer hoses (if equipped).
4. Detach transmission linkage from motor. Hold crank arm on the overlap two-speed motor with a wrench when removing or tightening linkage-to-crank nut.
5. Remove attaching screws and lower wiper motor from cowl.

Engine Section

ENGINE, REPLACE

When necessary to remove the engine from the car, disconnect the following items and raise the body off the engine and front suspension.

1. Front exhaust pipe from rear exhaust pipe.
2. Speedometer cable, front of propeller shaft and shift linkage from transmission.
3. Clutch and clutch equalizer on manual shift cars.
4. Wires, pipes, linkage, hoses, etc.
5. Stabilizer brackets from frame rail.
6. Front brake hoses.
7. Steering column from gear and raise up into steering column.
8. Remove air cleaner and carburetor cover.
9. Place a block of wood between front cross bar and front of engine oil pan. Remove rear transmission mount cross support and support rear of transmission with stand.
10. With front wheels on floor, remove the three isolation mount bolts and carefully raise body off engine and transmission, using care not to let suspension tip.
11. Reverse removal procedure to install.

CYLINDER READ, REPLACE

1. Drain cooling system.
2. Remove intake manifold.
3. Disconnect exhaust pipe.
4. Remove rocker arm cover.
5. When removing right cylinder head, remove generator rear mounting bracket bolt. Also remove ground straps at front and rear of head.
6. To remove left head, remove power steering belt and two pump bracket bolts from head.
7. Remove rocker arm assemblies and push rods.
8. Remove bolts and lift off cylinder heads.

Service Note

If equipped with a heater, the following steps should be taken when removing the right cylinder head:

1. Remove all head bolts except rear rocker arm shaft bracket bolt (blower motor prevents).
2. Loosen rear rocker arm bracket bolt and raise shaft assembly from head and remove push rods except No. 16.
3. Lift No. 16 push rod to within one inch of blower case and tape to rocker shaft.
4. Lift head, rocker shaft and exhaust manifold off dowel pins and move forward to clear blower case.

Fig. 1 Cylinder head tightening sequence

Installation

All cylinder head bolt threads must be coated with a suitable sealer. Torque head bolts in the sequence shown in Fig. 1 and to the specifications listed in the *Engine Tightening Chart*. Head gaskets should also be coated with a suitable sealer.

VALVE ARRANGEMENT

Front to rear . . . E-I-E-I-I-E-I-E

VALVES, REMOVE

1. With head removed, remove spark plugs and exhaust manifold.
2. Remove valve keys by compressing valve spring with a suitable spring compressor.
3. Remove spring retainers and springs and oil deflectors from valve stems. Remove valves from head, Fig. 2. Keep valves in a board with numbered holes so they can be replaced in their original position upon reassembly.

Cross section of engine

Fig. 2 Valve assembly

VALVES, GRIND

Clean the valve with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{1}{32}''$, otherwise the valve must be replaced.

Inspect the valve seats in the head for burns, cracks, pits, ridges or improper angle. During any general engine overhaul, it is advisable to reface valve seats regardless of their condition.

To assure satisfactory service, it is necessary that the valve seat widths be maintained at $\frac{1}{16}''$.

Engine lubrication

VALVE GUIDES

Clean the valve guides with a wire guide brush and check the clearance between valve stems and guides carefully. The standard clearances are given in the *Valve Specifications* table.

Excessive clearance between valve stems and guides will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

To check valve stem-to-guide clearance, take a new valve and place it in each valve guide and feel the clearance by moving the valve stem from side to side. If this check shows excessive clearance, it will be necessary to replace the valve guide.

If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

If it is necessary to replace valve guides, use a suitable driver to drive them out of the cylinder head. If suitable tools are not available, guides can be pulled out by using a piece of pipe together with a long bolt and washers.

Before removing guides, carefully measure the portion of the guide that protrudes from the cylinder head and install the new guides accordingly.

After the new guides have been installed, they should be reamed to provide the clearance given in the *Valve Specifications* table.

Valve guides are identified as follows:

Standard . . . . . No Groove
.001″ oversize . . . 2 Grooves
.010″ oversize . . . . 1 Groove
.011″ oversize . . . 3 Grooves

Standard guides should be replaced with .001″ oversize guides and .010″ guides should be replaced with .011″ oversize.

ROCKER ARMS

1. With rocker arm shaft assembly removed from head, remove cotter pins from ends of shaft.
2. Remove springs, arms and brackets from shaft.
3. If necessary to remove shaft end plug, punch hole in plug, then pry plug from end of shaft.
4. When assembling, refer to Fig. 3 and lubricate frictional surfaces of rocker arms and shaft with engine oil.
5. When installing, be sure to position rocker arm shaft over dowel in head.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 4. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

Fig. 4 Checking valve spring installed height

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16″, and since the acceptable valve head margin is approximately $\frac{3}{64}$″ to $\frac{5}{64}$″, one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

Fig. 3 Rocker arm shaft assembly

VALVE SPRING TESTING

Check valve spring tension on a suitable spring testing fixture if one is available. Fig. 5. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications in the *Valve Specifications* table within 10 percent should be replaced. Likewise any spring that stands shorter than the new spring used for comparison should be discarded.

HYDRAULIC VALVE LIFTERS

Failure of an hydraulic valve lifter is generally caused by an inadequate oil supply or dirt. An air leak at the intake side of the oil pump or too much oil in the engine will cause air bubbles in the oil supply to the lifters, causing them to collapse. This is a probable cause of trouble if several lifters fail to function,

Fig. 5 Testing valve spring pressure

Fig. 6 Hydraulic valve lifters

but air in the oil is an unlikely cause of failure of a single unit.

The valve lifters may be lifted out of their bores after removing the rocker arms and push rods. Adjustable pliers with taped jaws may be used to remove lifters that are stuck due to varnish, carbon, etc.

To disassemble, press down on the center of the push rod cup. Using a pointed tool, remove lock wire from the groove while holding cup down. Invert lifter and slide out push rod cup, plunger, ball retainer and spring.

To assemble, place the ball on its seat in the lower end of the plunger while holding the plunger upside down. Position the ball retainer and spring over ball and end of plunger. Lower the body over the plunger. Turn the assembly right side up and fill the plunger with clean engine oil. Jiggle the ball with a small piece of wire until oil drains out of plunger into the body and trapped air is released from the body. Refill the plunger with oil, place the push rod cup on the plunger and position the lock wire over the cup, locking it in its groove, Fig. 6.

TIMING CASE COVER

1. To remove cover, drain cooling system and disconnect water hoses and oil pressure switch wire.
2. Remove all belts, crankshaft and fan pulleys.
3. Remove distributor cap, vacuum hose, generator and bracket, Fig. 6A.
4. Remove fuel pump hoses, fuel pump and two front oil pan bolts.
5. Remove cover-to-block attaching bolts and remove cover, Fig. 6B.

Service Note

Whenever the front cover is removed it will be necessary to take off the oil pump cover and pack the space around the pump gears *completely full* of Petrolatum (vaseline). This step is very important as the oil pump may lose its prime when the cover is removed. If the pump is not packed it may not begin to pump oil as soon as the engine is started.

TIMING CHAIN

1. Remove distributor drive gear bolt, washer and gear from end of camshaft.
2. Remove fuel pump eccentric.
3. Remove crankshaft gear, chain and cam gear together by prying off crankshaft gear.
4. Install cam gear, crankshaft gear and chain together to align timing marks as shown in Fig. 7.
5. Install remaining parts and torque distributor drive gear bolt to 40-45 ft. lbs. Then install oil slinger and cover.

Fig. 7 Timing marks aligned for correct valve timing

Fig. 6B Engine front cover bolts

CAMSHAFT

1. To remove camshaft, remove grille, radiator, front cover, timing chain and gears, and intake manifold.
2. Remove rocker arm assembly, push rods and valve lifters.
3. Remove camshaft by carefully sliding it out of engine.
4. To provide initial lubrication when installing camshaft, it must first be coated liberally with engine oil.

CAMSHAFT BEARINGS

The camshaft bearings must be replaced in complete sets. All bearings

Fig. 6A Engine front cover component.

must be removed before any can be installed. The bearings may be removed by driving them rearward out of their bores with the exception of No. 5. This bearing must be removed by drilling a $\frac{3}{16}$" hole in the block at the bearing bore. Do not drill through the bearing. With a small punch, dent the bearing enough to allow it to be removed out the front of the bore.

When installing the bearings, install No. 5 first, then 4, 3, 2 and 1. Make sure that all oil passages are aligned.

PISTONS & RODS, REMOVE

1. Remove intake manifold, cylinder head or heads, and oil pan.
2. Examine cylinder bores above ring travel. If ridge exists, remove ridge with ridge reamer before attempting to remove pistons.
3. Before removing bearing caps, if rods are not marked with the cylinder number in which they operate, suitably mark them with the cylinder number for identification upon reassembly.
4. Remove bearing cap and bearing and push rod and piston up through top of cylinder bore.

PISTON & ROD, ASSEMBLE

Assemble pistons and rods as indicated in Fig. 8.

PISTONS

New pistons are furnished in standard size and .010" oversize. Since these are nominal or basic sizes it is important that new pistons be measured to insure proper fit. All new pistons are provided with selectively fitted piston pins, therefore, it is important to check the fit of the pin in connecting rod.

Fig. 8 Piston and rod assembly

Fig. 9 Checking bearing clearance with Plastigage

If the equipment required to measure fit of pistons in cylinder is not available, a fit can be satsfactorily checked by using a ½" x .0015" feeler ribbon and spring scale. When fitting pistons to cylinders by this method, the fit should be checked with the piston in the lower half of the cylinder, and both cylinder wall and piston clean and dry. The feeler ribbon should require a pull (in pounds listed in the chart) when drawn from between the piston (without rings) and cylinder wall.

If the pistons are to be reused with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an old piston ring, filing the broken end to a sharp, square edge and using it to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material.

Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Rinse the piston in solvent and wipe off the carbon on the sides of the piston. *Never use a wire brush to clean a piston* as the brush will round off the edges of the ring lands. Pistons showing scuffed or scored skirts should be scrapped. Examine the ring lands carefully for cracks. If the piston is in the least bit doubtful, it should be discarded.

PISTON PINS

The correct piston pin fit in the piston is .0003" to .0005" loose. If the pin-to-piston clearance is to the high limit (.0005") the pin can be inserted in the piston with very little hand pressure. The pin will fall through the piston by its own weight. The pin is a press fit in the connecting rod.

PISTON RINGS

When new piston rings are installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gaps of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with the lower end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of rings carefully with a smooth file.

ROD BEARINGS

Connecting rod bearings can be replaced without removing the rod assembly by removing the cap and replacing the upper and lower bearing halves. The clearance between the bearing and crankshaft can be measured with Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft and bearing.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the cap.
3. Reinstall cap and tighten to the torque value given in the *Engine Tightening Specifications* table.
4. Remove the bearing cap and determine bearing clearance by comparing the width of the flattened Plastigage with the graduation on the Plastigage envelope, Fig. 9. The number withing the graduation on the envelope indicates the clearance in thousandths of an inch. If clearance is excessive, replace the bearing.

Fig. 10 Tool for removing upper main bearing shells

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To Install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out, Fig. 10.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Tightening Specifications* table.

CRANKSHAFT OIL SEAL

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool, Fig. 11. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜″ from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

Fig. 11 Install rear main bearing oil seal

OIL PAN, REPLACE

1. Remove dipstick and drain oil.
2. Disconnect steering idler arm from relay rod.
3. Remove cover on front of lower flywheel housing and remove pan bolts.
4. On some types of lifts, it may be necessary to drop the oil intake into the pan before removing pan. The crankshaft should be positioned so the counterweights do not interfere with the pan's removal.

OIL PUMP REPAIRS

1. To remove pump, disconnect oil pressure switch.
2. Clean all dirt from pump-to-front cover joint; also around oil filter joint.
3. Remove oil filter and six pump cover-to-front cover screws.
4. Remove pump cover carefully as idler gear may fall out. Slide out idler and pump drive gears.

Inspection

1. Disassemble pump as indicated in Fig. 12. Wash all parts and blow out all passages with compressed air.
2. Inspect all parts for scoring. Small imperfections may be cleaned up with crocus cloth. *Do not break edges of valve.*
3. Check cover bore for cracks, nicks or warping.
4. Clearance between pressure relief valve and bore should be .0015-.0035″. Too much clearance can affect oil pressure at idle.
5. Check clearance of gears which shoud be .0015-.0075″.

Assembly

1. Install filter by-pass valve into output passage bore (passage with inside diameter ribs) seating squarely in bottom of passage.
2. Install remaining parts as shown in illustration. Tighten caps to 30-35 ft. lbs.
3. When assembled, fill gear pocket completely with petrolatum and force into every cavity of gear pocket; also between teeth of gears. *This step is very important. To assist in instant priming when engine is started, unless pump is packed as directed, it may not prime itself when engine is started.*

RADIATOR

1. Drain cooling system and remove upper radiator bracket.
2. Remove upper and lower hoses.
3. If equipped with Hydramatic, disconnect and cap cooler lines.
4. If equipped with air conditioning, loosen fan shroud and move rearward.
5. Loosen lower radiator support bolts and move supports rearward to allow radiator to be removed.

WATER PUMP

1. Drain cooling system and remove heater and lower hose from pump.
2. Loosen pulley belts and remove fan and pulley.
3. Remove nine pump-to-front cover bolts and take off pump. *Water pump is serviced only as an assembly.*

Fig. 12 Oil pump assembly

Fig. 13 Ignition details

DISTRIBUTOR, REPLACE

1. Disconnect primary wire from coil and remove distributor cap. If necessary to remove wires from cap, mark the position for No. 1 cylinder on the cap tower and reassemble as shown in Fig. 13.
2. Remove vacuum hose line from vacuum advance unit.
3. Remove hex head bolt and hold-down clamp.
4. Mark position of rotor; then pull distributor up until rotor just stops turning clockwise and note the position of the rotor at this point.
5. Remove distributor from front cover.

Installation

1. If engine was not disturbed while distributor was off, rotate rotor to same position as that at removal.
2. Install distributor into block and align distributor drive gear with oil pump drive shaft and camshaft gear. This can be done by rotating distributor drive shaft to first pick up oil pump drive shaft and then engage cam gear and distributor drive gear so that rotor is positioned as it was before removal after gear is engaged.
3. Complete the installation and check ignition timing.

IGNITION TIMING

Correct ignition timing exists when the timing mark on the vibration damper *(see Tune Up Chart)* is aligned with the timing indicator with engine running and with No. 1 piston up on its compression stroke.

STARTER, REPLACE

1. Disconnect battery positive cable.
2. Disconnect positive cable and starter cable from junction block and solenoid switch wire from chassis wiring harness.
3. Unfasten and remove starter from engine while sliding battery cable loom through cable support tube.

MUFFLERS & PIPES

Replacing any of the exhaust system components is a fairly obvious operation. However, before tightening any part of the system, align for adequate clearance between the body.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Rochester 2 barrel carburetor

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Carb-Airator adjustment

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve struck in either the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Then move the valve up and down a few times to work the oil in. *Do not use engine oil to lubricate the valve as it will leave a residue which hampers valve operation.*

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

Carb-Airator

This device (see cut) is an external breather attached to the carburetor on air-conditioned cars equipped with 2-barrel carburetor. Its purpose is to assist in reducing rich fuel and air mixture brought about during hot idling conditions.

Adjustments—Adjust normal idle with engine cool. When the engine is started, be sure the Carb-airator valve closes.

If the outside temperatures are extremely hot (95°) and the idle is rough or erratic, or stalling occurs, tighten the temperature screw one turn and road test. *Do not upset normal idle and do not* over-tighten temperature screw.

If the engine idles too fast under extreme hot conditions, tighten the air screw.

ROCHESTER CARBURETOR ADJUSTMENTS

Clutch and Transmission Section

CLUTCH PEDAL, ADJUST

1. Disconnect lower clutch control rod from equalizer, Fig. 1.
2. Adjust lower clutch control rod in or out of the trunnion nut to obtain ⅞″ to 1″ free travel of the clutch pedal.
3. Check free travel at the clutch pedal pad with the lower clutch control rod connected to the release yoke.

CLUTCH, REPLACE

1. Remove transmission.
2. Remove lower flywheel housing and release bearing.
3. Mark flywheel and clutch cover for reassembly and alternately loosen the six clutch cover attaching bolts two turns at a time to prevent distortion of the cover.
4. Install the clutch in the reverse order of removal and adjust clutch pedal free play.

SHIFT LINKAGE, ADJUST

1. Loosen trunnion nuts at bottom of steering column-to-equalizer and shift lever rods, Fig. 2.
2. Place hand selector lever and shift levers on transmission in neutral.
3. Position shift levers in steering column in alignment with each other as well as horizontal, and tighten trunnion nuts.

TRANSMISSION, REPLACE

1. Disconnect shift rods from levers.
2. Disconnect speedometer cable.
3. Disconnect propeller shaft from transmission companion flange. *Do not let front section of propeller shaft fall loose; move it to one side and tie it to exhaust pipe to avoid damage to center joint ball and seat.*
4. Support rear of engine with high floor stand.

Fig. 2 Adjusting shift linkage

Fig. 1 Clutch mechanism

5. Remove rear transmission mount and support bar.
6. Remove four transmission-to-clutch housing bolts.
7. Slide transmission straight back until main drive gear is free of splines in clutch disc.
8. Install transmission in reverse order of removal and adjust shift linkage.

TRANSMISSION REPAIRS

Disassembly

1. Referring to Fig. 3, remove top cover.
2. Remove front bearing retainer.
3. Remove retainer holding speedometer sleeve in rear bearing retainer, and remove driven gear and sleeve.
4. Remove companion flange from rear of transmission.
5. Remove rear bearing retainer.
6. Remove speedometer drive gear.
7. Drive countershaft-idler shaft lock plate from ends of shafts.
8. Drive countershaft rearward with a brass drift until shaft is just free in front shaft bore of case.
9. Using a suitable dummy shaft to hold bearings and thrust washers intact, allow countershaft to drop to bottom of case.
10. Remove main drive gear and bearing, and 14 pilot rollers from rear end of shaft.
11. Remove front bronze blocking ring from synchronizer. Remove snap ring from front of mainshaft.
12. Move mainshaft rearward until rear bearing is free of case. Then move mainshaft to extreme right of case, which will permit the 2nd-3rd shift fork to be removed.
13. Remove mainshaft by sliding shaft rearward through rear of case, at the same time stripping mainshaft as shaft is being withdrawn.
14. Remove 1st-reverse shift shoe from shift shaft. Drive reverse idler shaft out of case using a brass drift. Lift out reverse idler gear.
15. Lift cluster gear assembly from case.

Reassembly

During reassembly, apply a thin film of transmission lube to all parts. Always use new seals and gaskets. Refer to Fig. 3 and assemble the transmission in the following sequence:

Fig. 3 Exploded view of manual shift transmission

Countershaft Assembly

1. Install dummy shaft or Loading Tool J-8965 in cluster gear.
2. Insert tubular spacer.
3. Hold cluster gear in vertical position and while supporting loading tool from below, insert inner bearing spacer (washer) and place 22 rollers around loading tool, using heavy grease to hold them in place. Insert rollers on opposite end.
4. Install inner rear bronze thrust washer so that lugs engage notches in cluster gear. Install outer rear steel thrust washer. Large front thrust washer should not be installed at this time.

Synchronizer Assembly

1. Install springs solidly in recesses on both ends of synchronizer hub. One end of both springs should be located in same shift plate slot so that springs will extend in opposite directions from each other. Install shift plate directly over these ends.
2. While holding shift plates in their grooves, slide synchronizer sleeve over hub until detent is felt. The extended tapered portion of the sleeve faces the same direction (front) as the long extended portion at the center of the hub.
3. Place rear blocking ring in position at rear end of hub and rotate until shifting plates match notches in blocking ring. Blocking ring remains free until assembly of transmission.

Shift Levers & Interlock

Insert new seals and apply transmission lube in seals and shaft holes. Then install shift levers, interlock and related parts as indicated in Fig. 3.

When assembled, shift 2nd-3rd shift lever into 2nd speed position. With one end of interlock sleeve against 1st-reverse cam, the clearance between sleeve and 2nd-3rd cam should be .001-.007″. If clearance is greater than specified, and if it seems possible that the transmission can be forced into two gears at once, the old interlock sleeve should be measured with a micrometer and replaced with a new, longer sleeve. Sleeves are available in five lengths: 1.287″, 1.291″, 1.295″, 1.299″ and 1.303″.

Mainshaft & Main Drive Gear

1. Locate slinger washer on drive gear shaft with raised center portion toward front. Press bearing on shaft with outer snap ring groove toward front. Install bearing outer snap ring and thickest shaft snap ring that will properly seat in snap ring groove (three thicknesses are available).
2. Press bearing on rear of mainshaft with outer snap ring groove toward rear. Install bearing outer snap ring and shaft snap ring.
3. With bearing loading tool in place, and with cluster gear parts in place except front thrust washer, lower cluster gear assembly vertically through top of case with rear section of gear down. Then position cluster gear in horizontal position to allow front of cluster gear to pass projections in transmission case.
4. Locate cluster gear in normal position with lug on outer rear thrust washer up, and move loading tool rearward about ¼″ to pass into bore of case. Insert large front thrust washer with lug to front so as to engage slot in case. Align hole in washer with bore in cluster gear and move loading tool forward allowing cluster gear to drop to bottom of case.
5. End play of cluster gear should be .005″ to .017″ measured between two rear thrust washers. If clearance is excessive, replace thrust washers.
6. Locate reverse idler gear with hub section and chamfered side of teeth forward. Drive reverse idler shaft in through rear of case with lock plate slot toward countershaft bore. Leave shaft projecting about $\frac{1}{16}$″ from fully installed position.
7. Insert 1st-reverse shift shoe in its shift shaft and install mainshaft and bearing through rear of case. As shaft is being installed, slide 1st-reverse gear on shaft with groove on

Fig. 4 Throttle linkage with automatic transmission

gear toward front. Slide 2nd speed gear on shaft with extended portion toward front. With rear blocking ring in position, slide synchronizer on shaft with extended portion of sleeve toward front. Install mainshaft snap ring. Insert 2nd-3rd shift fork in its shaft and engage fork in groove in synchronizer sleeve. With 1st-reverse shoe offset toward front, engage shift shoe in groove on its gear. Move complete mainshaft assembly forward until rear bearing is fully installed in case bore.

8. With synchronizer hub and 2nd speed gear pressed forward against snap ring, there should be .003″ to .016″ end clearance between 2nd gear and front facing of 1st-reverse gear splines. Replace worn parts if clearance is excessive.
9. Place front blocking ring at front end of synchronizer hub and rotate until shift plates match notches in blocking ring.
10. Insert 14 pilot rollers in drive gear pocket, holding them in place with heavy grease.
11. Install drive gear and bearing through front of case, sliding bearing rollers in rear end of drive gear over front end of mainshaft.
12. Check clearance between front blocking ring teeth and drive gear teeth by lightly seating blocking ring on contacting surface of gear. Minimum clearance should be .045″. If less, replace blocking ring.
13. Turn transmission upside down to allow cluster gear assembly to drop to normal position. Align holes in case with cluster gear and drive out loading tool by installing countershaft. Leave countershaft projecting about $\frac{1}{16}$″ from fully installed position.
14. Install lock plate in slots of countershaft and reverse idler shaft. Then drive both shafts forward until lock plate is tight against the case.
14. Install front bearing retainer and gasket, being sure oil return hole in retainer and gasket match oil hole in case.
15. Complete the assembly by installing rear bearing retainer seal, speedometer drive gear, companion flange, speedometer driven gear and sleeve with new O-ring, and driven gear retainer.
16. Install top cover with gasket and check transmission in all shift positions.

AUTOMATIC TRANS.

Replace

1. Support engine.
2. Remove oil filler and breather tubes.
3. Remove propeller shaft and disconnect shift and throttle linkage, cooler lines and speedometer cable.
4. Remove exhaust pipe and transmission rear cross support bar.
5. Support transmission. Then remove attaching bolts and remove transmission from car.
6. Install in reverse order of removal. Lubricate transmission-to-engine attaching bolts and torque to 30-35 ft. lbs. Fill transmission with approved fluid and adjust linkage.

THROTTLE LINKAGE

With Two Bar. Carb.

1. To adjust, refer to Fig. 4, and disconnect lower T.V. rod from T.V. lever. With gauge shown in Fig. 5, check position of T.V. lever. Hole in lever must be within hole in gauge when holding lever rearward. If necessary, bend lever as required if gauge won't fit in holes. Connect T.V. rod to lever and lower car.
2. Disconnect upper and lower T.V. rods from T.V. bellcrank. While holding lower rod downward and bellcrank down at rear, clevis pin must be free. If not, adjust clevis. Then connect Lower T.V. rod to bellcrank.
3. Remove air cleaner and move throttle return dashpot out of the way.
4. Block choke valve open.
5. Back off idle adjusting screw until it is *not* touching fast idle cam when accelerator return spring is holding throttle valves closed.
6. With tool shown in inset, Fig. 4, on machined surface of manifold, top of accelerator rod should just touch tool. If necessary, bend auxiliary bellcrank link to adjust bellcrank.

Fig. 5 Checking throttle valve lever

Fig. 6 Adjusting throttle valve rods (4 barrel carb.)

Before attaching upper T.V. rod to bellcrank, check swivel to be sure it turns freely on threads.

7. Adjust T.V. rod "slightly short" and snap it onto ball stud.
8. While holding T.V. bellcrank against its stop, lengthen rod until swivel turns freely and feels "sloppy". Continue to lengthen rod by turning swivel until a very slight resistance is felt. At this point, upper rod is properly adjusted. Tighten lock nut while holding swivel in adjusted position.
9. Loosen throttle downshift stop screw lock nut and back off screw about six turns. With accelerator lever, move throttle to wide open position and over travel the linkage to point of maximum transmission of T.V. lever travel.
10. Back out throttle stop screw a few turns. Then while holding accelerator lever in wide open position, set stop screw to just touch downshift lever tang and preload it by turning screw an additional 1½ turns.
11. Run engine until it reaches normal operating temperature and adjust idle speed with transmission in "Drive".
12. With engine shut off, check and adjust pedal height as shown in Fig. 7.
13. Reposition throttle return dashpot and adjust stop screw to obtain .020" clearance between screw head and plunger with idle screw on high step of fast idle cam.

With Four Bar. Carb.

1. Raise car on hoist.
2. Disconnect lower T.V. rod from T.V. lever and position gauge as shown in Fig. 5. If the hole in the lever does not fall within the gauge hole, bend the lever as required.
3. Lower car and disconnect upper T.V. rod from T.V. bellcrank (see Fig. 4).
4. Disconnect lower T.V. rod from T.V. bellcrank.
5. While holding lower T.V. lever downward and T.V. bellcrank down at rear, the clevis pin must be free. If necessary, adjust clevis and connect lower T.V. lever to bellcrank.
6. Remove air cleaner and pivot throttle return check (dashpot) out of the way. Block intermediate choke lever to release fast idle cam.
7. Back off idle adjusting screw until it is *not* touching stop when accelerator return spring is holding throttle valves in closed position.
8. Bend auxiliary bellcrank link to obtain .020 to .040" between auxiliary bellcrank and gauge surface of carburetor throttle body.
9. Adjust upper throttle valve rod "slightly short" and snap it onto ball stud. Then lengthen rod until a clearance of .002 to .005" is obtained at throttle valve bellcrank, Fig. 6.
10. Loosen throttle downshift stop screw lock nut and back off screw approximately 6 turns. With the accelerator lever, move throttle to wide open and over-travel the linkage to the point of maximum transmission throttle valve lever travel. *Do not bend or stretch linkage.*
11. With accelerator lever in wide open position, set stop screw so it just touches downshift lever tang; then turn screw an additional 1½ to 2 turns.
12. Remove block from intermediate choke lever. Start and allow engine to reach operating temperature. Adjust slow idle to 500 rpm and fast idle to 1600 rpm.
13. Adjust pedal height as shown in Fig. 7. Reposition and adjust dashpot plunger length to obtain .020" gap between plunger and lever.

Fig. 7 Adjusting accelerator pedal height

Rear Axle & Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

REAR AXLE

As shown in Fig. 1, the drive pinion is mounted on two tapered roller bearings that are preloaded by two selected spacers. The drive pinion is positioned by shims located between a shoulder on the pinion and the rear bearing. The front bearing is held in place by a large nut.

The differential is supported in the carrier by two tapered roller side bearings. These are preloaded by inserting shims between the bearings and the pedestals. The differential assembly is positioned for ring gear and pinion backlash by varying these shims.

Axle Shaft, Replace

1. To remove the axle shafts, Fig. 1, take off the wheels. *Note that the left side wheel bolts have left hand threads and the nuts are marked "LH".*
2. Remove brake drums.
3. Remove nuts holding retainer plates to brake backing plates. Pull retainers clear of bolts and reinstall two lower nuts finger tight to hold brake backing plate in position.
4. Pull out axle shafts using a puller and adapter with a slide hammer. *While pulling axle shaft out through oil seal, support shaft carefully in center of seal to avoid cutting seal lip.*
5. Reverse removal procedure to install axle shafts. Note that the left shaft is shorter than the right shaft. Apply wheel bearing grease in the bearing recesses of the housing. Install new outer retainer gaskets. Insert axle shaft carefully until shaft splines engage in differential to avoid damage to seals. Torque retainer stud nuts to 60 ft. lbs.

Axle Shaft Bearing

1. With axle shaft removed, nick bearing retainer in three or four places with a chisel deep enough to spread ring. Retainer will then slip off.
2. Press bearing off shaft. An arbor press may be used.
3. Press new axle shaft bearing against shoulder on axle shaft. *Retainer plate which retains bearing in housing must be on axle shaft before bearing is installed; retainer gasket can be installed after bearing.*
4. Press new retainer ring against bearing.

Axle Shaft Seal

1. Insert axle shaft so that splined end is just through seal.

2. Using axle shaft as a lever, push down on shaft until seal is pried from housing.
3. Apply sealer to O.D. of new seal.
4. Position seal over a suitable installer and drive seal straight into axle housing until fully seated.

Rear Axle Repairs

Disassembly and assembly of the differential case, replacing the ring gear, checking ring gear and pinion backlash and other differential case operations are given in the *Rear Axles Chapter*. The following operations are significant for this type rear axle.

Side Bearing Preload

After the differential case has been assembled, differential side bearing preload is adjusted by changing the thickness of both the right and left shim by an equal amount. By changing the thickness of both shims equally, the original backlash will be maintained. Differential adjustment shims are available in thicknesses ranging from .040″ to .082″ in .002″ increments.

In order to adjust side bearing preload accurately, adjustment should be made before the pinion is installed. This allows the ring gear and case assembly to be rotated freely.

Place differential case and bearing assembly in carrier. If new side bearings are installed, use original adjusting shims; if same bearings are to be reused, select new right and left adjusting shims each .002″ thicker than the original shim. Slip right shim in position at right bearing, then drive left shim carefully into position using a soft hammer.

Rotate differential case several complete turns to seat bearings. Check bear-

Propeller shaft and universal joints

Fig. 1 Rear axle assembly

ing preload with an inch-pound torque wrench applied to a ring gear attaching bolt. With torque wrench projecting approximately straight out, bearing preload should read 20-30 inch lbs. with new bearings and 10-20 inch lbs. with reused bearings. If preload is not within these limits, increase shim thickness .002″ on each side for each added 10 inch lbs. preload desired, or decrease shim thickness .002″ on each side for each 10 inch lbs. preload to be subtracted.

When adjustment is satisfactory, remove differential, keeping bearing caps and shims together so that they may be reinstalled properly after the drive pinion has been installed.

Drive Pinion Preload

If new pinion bearings are installed, use the original pinion preload spacers. If the same bearings are being reused, select a pair of pinion preload spacers having a total thickness of .002″ less than the original spacers. Install spacers on pinion and position pinion in carrier. Pinion preload spacers are furnished to be used in pairs so that the possible combined thickness range from .400″ to .470″.

Install pinion and bearings and new oil seal. Install flange and nut, torquing nut to 200 ft. lbs. Rotate pinion several times to seat bearings.

Check bearing preload using an inch pound torque wrench applied to the pinion nut. The preload reading including drag of new seal should be 25-35 inch pounds with new bearings or 15 to 25 inch pounds for reused bearings. If preload torque is not within these specifications, reduce the total pinion spacer thickness .001″ for each 10 inch pounds preload desired, or decrease total pinion spacer thickness .001″ for each 10 inch pounds preload to be subtracted.

MASTER CYLINDER, REPLACE

Be sure area around master cylinder is clean, then disconnect hydraulic line at master cylinder. Plug or tape end of line to prevent entrance of dirt.

Remove four attaching nuts and remove master cylinder. It is not necessary to disconnect the push rod and clevis.

Install master cylinder, fill reservoir with fluid and bleed system.

Front End & Steering Section

WHEEL ALIGNMENT

Caster & Camber

Caster and camber is adjusted by shimming at the upper control arm shaft attaching points. These shims are available in thicknesses of .030″, .060″ and .120″.

Adding shims at the front locations will change caster toward negative with practically no change in camber. Adding shims at the rear locations will change caster toward positive and camber toward negative. Adding equal shims at both front and rear locations will not change caster but will change camber toward negative.

To adjust, loosen both front and rear bolts to free shims for removal or addition. After installing or removing shims (limit to .380″ in any one stack) tighten and torque shaft bolts to 60-85 ft. lbs.

Toe-In, Adjust

Car must be at curb weight and running height; bounce front end and allow it to settle at running height. Steering gear and front wheel bearings must be properly adjusted with no looseness at tie rod ends. The car should be moved forward one complete revolution of the wheels before the toe-in check and adjustment is started and the car should never be moved backward while making the check and adjustment.

With front wheels in the straight ahead position, toe-in is adjusted by turning the tie rod adjusting sleeves as required. Left and right adjusting sleeves must be turned exactly the same amount but in opposite directions in order to maintain front wheels in straight ahead position when steering wheel is in straight ahead position.

The steering knuckle and steering arm "rock" or tilt as front wheel rises and falls. Therefore, it is vitally important to position the bottom face of the tie rod end parallel with the machined surface at the outer end of the steering arm when

Fig. 1 Front suspension assembly

Fig. 2 Steering gear worm and ball nut

tie rod length is adjusted. Severe damage and possible failure can result unless this precaution is taken. The tie rod sleeve clamps must be straight down to provide clearance.

WHEEL BEARINGS, ADJUST

1. Tighten spindle nut to 10-15 ft. lbs. torque and rotate hub to seat bearings.
2. Back off 1/6 turn minimum to ¼ turn maximum to allow installation of cotter pin.
3. Before installation of grease cap in hub, make sure end of spindle and inside of cap are free of grease so that radio static collector makes good contact. Make sure that static collector is properly shaped to provide good contact between end of spindle and grease cap.

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure the front wheel bearings are properly adjusted and that the control arms are tight. Then check joints for wear as follows:

To check lower joint, jack up the car at the frame side rails on each side. Set up a dial indicator at the lower vertical edge of the wheel. Then with one hand at the top and the other at the bottom of the tire, rock the wheel at top and bottom. If more than 1/16″ movement appears on the dial indicator, the lower ball joint should be replaced.

To check the upper ball joint, disconnect it from the steering knuckle. Install nut on ball joint stud and, using an inch pound torque wrench, rotate the stud in a clockwise direction. The reading should be 2 to 30 inch pounds. If not within these limits, the upper ball joint should be replaced.

FRONT END REPAIRS

Ball Joints, Replace, Fig. 1

1. Loosen (do not remove) stud nut.
2. Rap knuckle sharply in area of stud to disengage stud from knuckle.
3. Support lower control arm with jack and remove (loosened) nut from stud. Raise upper control arm to remove stud from knuckle.
4. Tie brake backing plate and steering knuckle out of the way.
5. Remove ball joint from control arm.
6. Install new ball joint into control arm and tighten until hex section of ball joint seats firmly into arms.
7. Turn tapered stud until cotter pin hole is fore and aft and assemble rubber dust shield over stud.
8. Assemble knuckle and backing plate and torque castellated nut to 35-60 ft. lbs.

Shock Absorber, Replace

Unfasten shock absorber top and bottom and remove it through the spring seat. Check shock absorber for obvious physical damage or oil leakage. Push and pull shock absorber in an upright position. If smooth hydraulic resistance is not present in both directions, replace shock absorber.

Spring, Replace

1. Remove wheel with hub and drum.
2. Disconnect stabilizer link from lower control arm and remove shock absorber.
3. Disconnect lower control arm ball joint from steering knuckle.
4. Lower floor jack under spring until spring is fully extended and remove spring.
5. To install spring, tape spring insulator to top of spring (identified by a ground flat coil). Rotate spring so end of bottom coil will index with edge of hole in lower control arm spring seat. Complete the installation in the reverse order of removal.

Upper Control Arm

1. Disconnect upper ball joint from steering knuckle.
2. Remove control arm, carefully noting number, location and thickness of adjusting shims between shaft and frame bracket.
3. If shaft and bushings only are to be replaced, clamp control arm in vise and remove shaft and bushings.
4. Assemble new grease seals on shaft. Apply light coating of grease to shaft threads and position shaft in arm. Start new bushing in arm and thread shaft into bushing to aid in alignment. Tighten bushing into arm until hex section of bushing seats firmly into arm.
5. Start second bushing into threads of arm with shaft threaded into opposite bushing.
6. After bushing has been threaded part way into arm, rotate shaft to engage threads of second bushing as and aid in piloting bushing squarely into position.
7. Tighten bushing into arm until hex section of bushing seats firmly into arm. Shaft should be free enough to turn by hand. Install grease fittings and lubricate bushings.
8. Rotate shaft to make distance between shaft bolt holes and arm equal on both sides as nearly as possible.
9. Assemble upper control arm assembly, making certain the wheel alignment shims are correct. Torque shaft-to-bracket bolts to 60-85 ft lbs.
10. Assemble ball joint.
11. Check and adjust wheel alignment if necessary.

Fig. 3 Steering gear pitman shaft and ball nut

Fig. 4 Steering shaft coupling

Lower Control Arm

1. Remove coil spring.
2. Remove threaded bushings from control arm and remove arm from shaft.
3. Lightly coat shaft threads with grease and install rubber seals on shaft.
4. Position control arm on shaft and start front bushing onto shaft threads. Place a suitable spacer between control arm and crossmember to maintain control arm spread.
5. Thread front bushing into control arm. Tighten bushing until hex of bushing seats firmly into arm.
6. Remove spacer and install rear bushing as above.
7. Install coil spring.

HORN SOUNDER & STEERING WHEEL

1. To remove Standard wheel cap, loosen attaching screw by inserting

Fig. 5 Steering gear adjusters

screwdriver through access hole in side of cap. With screw loosened, cap can slide off steering wheel.

2. The Deluxe cap is held in place by spring steel clips. To remove cap, pry it from wheel.
3. Disconnect horn wire. Remove nut and use puller to remove steering wheel.

MANUAL STEERING GEAR

The steering gear is the recirculating ball worm and nut type, Fig. 2. The teeth on the pitman shaft sector are slightly tapered so that a proper lash may be obtained by moving the pitman shaft endways by means of a lash adjuster screw which extends through the gear housing side cover, Fig. 3. The outer race or cup of the lower worm bearing is pressed into the worm bearing adjuster which screws into the housing and is locked by a nut, Fig. 2. The upper steering shaft is connected to the steering worm shaft through a universal joint type coupling, Fig. 4.

Steering Gear, Adjust

Never attempt to adjust the steering gear while it is connected to the intermediate rod. The steering gear must be free of all outside load to properly make any steering gear adjustments.

1. Torque steering gear-to-frame bolts to 45-60 ft. lbs.
2. Disconnect relay rod from pitman arm.
3. Turn steering wheel slowly from one extreme to the other. *Never turn wheel hard against end stops as damage to ball nut may result. If gear is hard pulling or binding it indicates an excessively tight adjustment of worm bearings or excessive misalignment of steering shaft. Roughness of gear indicates faulty internal parts. These conditions must be corrected before steering gear can be properly adjusted.*
4. Attach a spring scale and measure pull at wheel rim required to keep wheel in motion at about one turn of wheel from either extreme position. Pull required should be ¼ to ¾ lb. If not within these limits, adjust worm bearing preload as follows:
5. Loosen worm bearing adjuster lock nut, Fig. 5. Turn bearing adjuster as required to bring wheel pull between ¼ to ¾ pounds. Tighten lock nut and recheck adjustment.
6. To check pitman shaft overcenter preload, turn steering wheel from one extreme to the other while counting the total turns; then turn wheel back ½ the number of turns. This positions gear on the high point where a preload should exist between ball nut and pitman shaft teeth.
7. A pull of ⅞ to 1½ lbs. should be required to turn the wheel through the high point. Loosen the lock nut and turn the pitman shaft lash adjuster, Fig. 5, as required to obtain ⅞ to 1½ lbs.
8. After tightening lock nut, rotate steering wheel back and forth through the high point and through the entire range to check for tight spots. *If lash cannot be removed at high point or if gear load varies greatly and feels rough, the gear should be removed for inspection of internal parts.*

Steering Gear, Replace

1. Remove steering shaft coupling clamp bolt and slide clamp off coupling housing onto steering gear worm shaft. Mark steering shaft in line with slot at coupling clamp surface.
2. Disconnect horn wire from harness. Remove horn shroud from center of steeing wheel.
3. Pull off steering wheel.
4. Pull horn contact plate out of recess in actuator to give clearance for removal of upper bearing retainer clip. Pry clip out of actuator housing.
5. Pull steering shaft out of steering column and block shaft up about two inches.
6. Remove left-hand end plug from relay rod and pull relay rod off pitman arm.
7. Remove four bolts attaching gear to suspension cross bar and remove gear from car.
8. Reverse removal procedure to install gear (see Fig. 6). Torque pitman shaft nut to 100-125 ft. lbs. Torque gear attaching bolts to 45-50 ft. lbs.

Steering Gear Repairs

Using Fig. 7 as a guide, disassemble the steering gear, observing the following:

Fig. 6 Correct worm to lower coupling attachment

1. The lower worm bearing cup is not replaced separately but is serviced with the worm bearing adjuster.
2. If the side cover bushing is worn, the side cover must be replaced as the bushing is not furnished separately.
3. Inspect teeth of ball nut and pitman shaft for pitting or scoring which would require replacement of nut or pitman shaft.
4. Check pitman shaft surface for wear or scoring, then check fit of lash adjuster and shim in the slot in end of pitman shaft by inserting a feeler gauge between head of screw and bottom of slot. Adjuster must be free to turn and end play should not exceed .002″. If end play exceeds .002″, install proper shim. Shims are available in thicknesses of .063″, .065″, .067″, and .069″.
5. Lubricate all seals, bushings, bearings and gears with multi-purpose gear lube just before assembling.

Fig. 7 Exploded view of manual steering gear

Steering Gear, Assemble

1. Position ball nut over worm shaft so that deep side of teeth will be toward side cover when installed in gear housing.
2. Install 19 balls in each circuit. Rock worm shaft slightly to aid in installing balls.
3. Place 6 balls in each return guide, using grease to hold balls in place.
4. Install return guides, clamp and screws.
5. Rotate worm through its complete travel several times to insure balls are installed correctly and rotate freely.
6. Place upper bearing on worm shaft into housing.
7. Place lower bearing in worm bearing adjuster and install bearing retainer.
8. Install adjuster with lock nut in housing. Tighten adjuster only enough to hold worm bearings in place.
9. Turn worm shaft until center groove in ball nut lines up with center of pitman shaft bushing. Install pitman shaft and lash adjuster with shim so that center tooth meshes with center groove in ball nut.
10. Install side cover with new gasket on lash adjuster by turning adjuster counterclockwise. Install and torque side cover bolts to 30 ft. lbs.
11. Turn lash adjuster so that teeth on shaft and ball nut engage but do not bind. Install lash adjuster lock nut loosely.
12. To protect pitman shaft seal from damage, cover shaft splines with masking tape. Slide new seal into place and seat against shoulder in housing.
13. Install new worm shaft seal flush with surface of housing.
14. Fill gear with multi-purpose lubricant, install on car and adjust as previously described.

POWER STEERING

Service procedures on the power steering gear are given in the *Power Steering* chapter. To remove the gear from the car, proceed as follows:

1. Remove coupling flange nuts, and ground wire from flange attaching bolt.
2. Disconnect hoses from pump and gear. Cap pump, hose fittings and gear connectors.
3. Disconnect horn wire from harness. Remove horn shroud from center of steering wheel. Pull off wheel. Pull horn contact out of recess in actuator to give clearance for removal of upper bearing retainer clip. Pry clip out of actuator housing.
4. Pull steering shaft out of steering column and block shaft up about two inches.
5. Disconnect relay rod from pitman arm. Remove four bolts attaching gear to front suspension cross bar and remove coupling from gear.
6. Reverse removal procedure to install, tightening gear attaching nuts to 45-60 ft. lbs.

Instruments, Radio & Windshield Wiper

INSTRUMENT CLUSTER

All instruments and speedometer can be serviced after the instrument cluster has been removed. The procedure is as follows:

1. Disconnect battery positive cable.
2. Remove cluster attaching screws.
3. Disconnect wiring harness, clock and speedometer cable at cluster.
4. Remove four attaching nuts from under instrument panel and remove cluster from top of instrument panel.

RADIO REMOVAL

1. Disconnect radio lead from wiring harness.
2. Disconnect antenna lead-in and speaker wire.
3. Remove control knobs, escutcheons and nuts from front of instrument panel.
4. While supporting radio to prevent it from falling, disconnect radio rear bracket from radio and remove radio.

WINDSHIELD WIPER

1. To remove wiper motor, disconnect drive link from crank arm under instrument panel by removing retaining clip.
2. Disconnect harness connector from motor terminals.
3. If equipped with windshield washers, note location of hoses, then remove hoses from washer pump.
4. Remove three attaching screws and lift motor from cowl, guiding crank arm out of hole in cowl panel.

①—V8 cylinder numbering (front to rear): Left bank 1-3-5-7, right bank 2-4-6-8.

②—When cranking engine first line to come under pointer is for standard head and second line for high compression head.

③—When cranking engine second line to come under pointer.

④—When cranking engine first line to come under pointer.

⑤—With Hydramatic 139, with standard trans. 123.

⑥—With standard head 120, with H. C. head 145.

⑦—Turn adjusting screw in (clockwise) until engine begins to misfire. Then turn screw out ½ turn.

⑧—4° BTDC for Tempest 420-E engine only.

⑨—Add 50 RPM to idle speed if equipped with air conditioner, with air conditioner off.

Engine Section

Engine cross section (one block). 1955 V8. After 1955 removable valve guides are not used

ENGINE, REPLACE

In addition to the usual items such as radiator, hood, battery, propeller shaft, lines and linkage, it will be necessary to perform the following operations:

1. On 1955-56, remove engine right side apron.
2. Disconnect exhaust pipe from crossover pipe.
3. On manual shift cars, disconnect linkage from clutch and remove clutch control countershaft bracket from flywheel housing.
4. Thread a chain through openings in intake manifold behind carburetor. Attach chain to a hoist and raise engine just enough to take weight off mounts.
5. Unfasten mountings from crossmembers.
6. On Hydra-Matic cars, support transmission with a jack and remove frame crossmember to which rear engine mounts are fastened.
7. Hoist engine and transmission as a unit.
8. Reverse above procedure to install. However, on Hydra-Matic cars it will be necessary to raise rear of engine to install the crossmember.

CYLINDER HEAD

1. Remove intake manifold.
2. Remove push rod cover.
3. Remove rocker arm cover.
4. Remove battery ground strap from left head or engine ground strap from right head.
5. Remove Hydra-Matic oil level indicator tube bracket and engine oil level indicator and tube from right head (1955-57 and 1961-62).
6. Loosen all rocker arm adjusting nuts and move rocker arms off push rods.
7. Remove push rods and place in a suitable stand so they can be replaced in exact position from which they were removed. *No. 7 exhaust valve push rod (rearmost on left bank) cannot be removed on 1955-57 cars with defroster. In this case withdraw rod part way and fasten it to head.*
8. Remove screws attaching exhaust crossover pipe to manifold.
9. Remove screws from cylinder head water inlet fitting.
10. Remove cylinder head screws and remove head with exhaust manifold attached. *If left head is being removed, it will be necessary to raise head off dowel pins, move it forward and shift it in order to clear the defroster, power steering and power brake equipment.*

Installation

Right and left heads are the same except for the location of the water passage plug in end of water passage. Therefore, only one head is provided for service replacement. New heads are complete with valve guides, rocker arm studs and all plugs except the one water passage plug.

When installing a new head, ream the valve guides and check the concentricity of valve seats. Transfer all serviceable parts to the new head, using new seals on the intake valve stems and new exhaust manifold gasket. Install new water passage plug using gasket cement, and install new intake manifold mounting studs.

Install the head in the reverse order of removal. The head screws are three different lengths. When inserted in the proper holes all screws will project an equal distance from the head. Do not use sealer of any kind on the threads. Tighten screws evenly to the torque given in the *Engine Tightening Chart.*

Use four thin (.075″) gaskets or two thick (.135″) gaskets when installing the exhaust crossover pipe to the exhaust manifold.

VALVE ARRANGEMENT

Front to rear .....E-I-I-E-E-I-I-E

VALVES, ADJUST

1955

Whenever rocker arms, push rods and valve lifters are removed, an initial setting of the rocker arm nuts must be made to establish the correct operation

of the valve train.

Install the lifters in the bores from which they were removed. Install push rods and rocker arms with balls and start rocker arm nuts. *Push rods should be installed in same places they were originally installed and with same end contacting rocker arm.*

The self-locking rocker arm nuts should be adjusted as follows to properly position the plungers within the lifters. Each rocker arm nut must be adjusted when the corresponding valve is completely closed. The simplest and most accurate way to make this adjustment is to adjust one cylinder at a time while it is in the firing position.

With distributor rotor pointing to firing position for No. 1 cylinder, tighten No. 1 intake and exhaust rocker arm ball nuts, one at a time, just until there is no up and down movement of the push rod (do not depress lifter plunger). When rocker arm movement has just been eliminated, tighten rocker arm ball nut *one complete turn.* This will depress the plunger the proper amount within the lifter.

Turn the crankshaft and adjust each set of rocker arm nuts according to the firing order of the engine in the same manner as outlined above.

Service Note

To be sure that the valves and lifters function perfectly, it is strongly recommended that a vacuum gauge be used when tightening rocker arm nuts. With vacuum gauge connected and engine idling, tighten each rocker arm nut until the *highest and steadiest vacuum reading is indicated on the gauge.*

1956-62

No valve adjustment is required on these engines due to the new valve train. This was accomplished by moving the valve lifter oil supply hole nearer the top of the lifter body to insure ample oil reserve, along with the new design of the rocker arm ball retaining nut and rocker arm mounting stud.

ROCKER ARM STUD

Rocker arm studs are replaceable providing a press of two tons capacity or more is available.

1. Remove cylinder head.
2. Remove rocker arm.
3. Pull out rocker arm stud by using washers or other suitable shims under the nut.

Installation, 1955

1. Ream out hole, Fig. 1. *Service replacement studs are .003" oversize.*
2. Remove plugs from ends of cylinder head oil gallery and thoroughly clean out metal deposits and foreign matter from oil gallery.
3. Position rocker arm on new stud and place Stud Installer J-5716, Fig. 2, on stud in place of rocker arm ball.
4. Coat stud with white lead and oil, and with cylinder head mounted in press on Tool No. J-5712 so studs are vertical, position new stud with rocker arm and stud installer over hole in head.
5. Press stud into head until it is in about halfway ($\frac{7}{16}$").
6. Position Valve Train Gauge J-5710, Fig. 3, in push rod hole so that it seats properly in rocker arm.
7. With valve seated, slowly press stud into cylinder head until the gauge is positioned as shown in Fig. 3.
8. Blow air through hole in stud to be sure passage is not restricted.
9. Reinstall parts removed and install head.

Installation, 1956-62

To install a new rocker arm stud in the cylinder head, a special Rocker Arm Stud Installer and a special Valve Train Gauge should be used, following the procedure outlined for 1955 models.

When the valve rocker arm ball retaining nut is tightened to a torque of 15-25 ft. lbs., proper location of the rocker arm with respect to the push rod and valve lifter is automatically assured.

Engine lubrication

Fig. 2 Pressing in new rocker arm stud

Fig. 1 Reaming rocker arm stud hole

Fig. 3 Gauge should be positioned as shown when stud is properly installed

Fig. 4 Driving out valve guide. 1955

The need for adjusting rocker arm position as in 1955 is thereby eliminated.

Service Note

In the event that the nut can be turned down to the point where the required 15-25 ft. lbs. of torque cannot be obtained, probably the stud has worked itself up out of position. If such is the case, run the nut all the way up flush with the top of the stud threads and hammer the stud down with a brass drift to get the threads nearer to the cylinder head casting, which should permit the proper torque to be obtained.

VALVES, REMOVE

With cylinder head removed as outlined previously, use a suitable valve spring compressor to compress the spring in order to take out the valve locks. Then remove spring retainers, valve stem cup seals (intake valves only) and valve springs. Remove burrs from valve stem lock grooves to prevent damage to valve guide holes and slide valves from heads.

Place the valves in a board with numbered holes to identify their location so that, if re-used, they can be returned to their original guide holes.

Fig. 5 Correct installation of valve guide. 1955

VALVE GUIDES

1955

1. Drive out old guide, Fig. 4.
2. Drive new valve guide into place from combustion side of cylinder head as follows:
3. Coat outside of valve guide with white lead or oil.
4. Start chamfered end of guide into its hole and drive into cylinder head with the tool shown in Fig. 4 until the end of the guide is positioned as shown in Fig. 5. Use the depth gauge shown in Fig. 6 to measure this distance.

1956

Valve guides are cast integral with the cylinder head and are tapered as in the past. Some cylinder heads may be equipped with one or more 1955 removable type valve guides. These valve guides are installed in production if the integral valve guides are reamed oversize in the machining operation.

If necessary to service a guide to accommodate either the .001″ or .003″ oversize valve stem, use the proper reamer, Fig. 10. If replacement of a removable type guide is necessary, use the procedure outlined for 1955 models.

Since valve guides taper .0015″ to the inch, a tapered reamer, Fig. 7, must be used to ream the guides to provide the correct taper and correct valve fit. Correct fit of valve stem in guide is such that when valve is started in guide it will just drop through of its own weight, but will have no perceptible side play.

Since this is a tapered reamer, the hole in the valve guide will become larger as the reamer is turned down. To avoid reaming oversize, when using the type reamer shown in Fig. 7, set the sliding stop to 3″ from the end and ream until the sliding stop bottoms. Then move the stop back to 3¼″ from the end and carefully continue reaming a little at a time, alternately reaming and testing the valve stem fit until the exact fit is obtained.

1957-62

Unlike previous models the valve guides are straight (not tapered). Valves with oversize stems are available in .001″, .003″ and .005″. Valve stem clearance is given in the *Valve Specifications* chart. The same clearance applies for oversize stems. Oversize reamers are required to enlarge the valve guide holes to fit the oversize valve stems. When the reamer is turned through the valve guide it will size the hole to fit the valve stem according to the clearance specifications. The tolerance for the oversize valve stem is controlled so that they will automatically fit properly in the hole after it is reamed. For best results when installing .005″ oversize valve stems, use a .003″ oversize reamer first and then ream to .005″ oversize. *Always reface the valve and valve seat after reaming valve guide.*

Fig. 6 Checking position of valve guide with depth gauge. 1955

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Figs. 8 and 9. If the assembled height is greater than the dimension given in the *Valve Specifica-*

Fig. 7 Reaming valve guide with tapered reamer, 1955-56. After 1956, valve guides are straight

tions Chart, install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16", and since the acceptable valve head margin is approximately $\frac{3}{64}$" to $\frac{5}{64}$", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

After taking out the valve springs, wash them in suitable solvent or gasoline. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available, and according to the specifications given in the *Valve Specifications* chart. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

Cylinder block and related parts. V8 engine

VALVES, GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the valve heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. This condition leads to premature breakage, burning or pre-ignition due to heat localizing on this knife edge. If the edge of the valve head is less than $\frac{1}{32}$" thick after grinding, replace the valve.

Reface valves to 44 degrees for exhaust and 29 degrees on the intake valve; true up valve seats to 45 degrees on the exhaust and 30 degrees on the intakes. Cutting a valve seat results in lowering valve spring pressure and increases the width of the seat. The normal width of a valve seat is $\frac{3}{64}$" to $\frac{1}{16}$".

Test valves for concentricity with seats and for tight seating. Valves can be tested by lightly coating the valve face with prussian blue and turning the valve against its seat. This indicates whether the seat is concentric with the valve guide *but does not prove that the valve face is concentric with the valve stem, or that the valve is seating all around.* After making this test, wash all blue from the surfaces, lightly coat the *valve seat* with blue and repeat the test to see whether a full mark is obtained on the valve. *Both tests are necessary to prove that a proper seat is being obtained.* If a dial gauge is used to check the concentricity of valve seats, the concentricity should be held within .002".

When valves and seats are reground, the position of the valve in the head is changed so as to shorten the operating length of the hydraulic lifter. This means that the plunger is operating closer to its bottom position, and less clearance is available for the thermal expansion of the valve mechanism during high speed driving.

To check and correct the length of the valve stem after grinding valves, position the rocker arm on the stud and hold in place with Special Rocker Arm Stud Installer, Fig. 10. Slip the valve into place and hold it against the valve seat. While holding the rocker arm and valve in position securely, insert Special Valve Train Gauge, Fig. 10, through push rod hole

Fig. 8 Checking installed height of valve springs. Engines with removable guides

Fig. 9 Checking installed height of valve springs. Engines with integral guides

Fig. 10 Checking length of valve stem

and seat snugly in push rod of rocker arm. With all parts seated, step end of gauge should be at least flush with gasket face of head but should not project past the step on the gauge, as shown.

If the gauge projects too far, indicating that the valve stem is too long, grind the tip of the valve stem as necessary to make the gauge index properly. *Do not overheat the valve stem when grinding as excessive heat will soften the hardened stem, causing rapid wear.*

VALVE LIFTERS

See the *Trouble Shooting Chapter* under the heading *Engine Noises* for causes of hydraulic valve lifter noise.

The easiest method for locating a noisy valve lifter is by the use of a piece of garden hose about 4 feet long. Place one end of the hose near each valve in progression and listen through the other end. In this manner the sound is localized, making it easier to determine which lifter is at fault.

Another method is to place a finger on the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be removed and cleaned. If dirt, varnish or carbon is found to exist in one unit, it more than likely exists in all the units.

Removal

Remove intake manifold, push rod cover and rocker arm cover. Loosen rocker arm ball nut and move rocker arm off push rod.

Remove push rod. *The rearmost push rod in the left bank cannot be removed on 1955-57 with defroster unit. In this case the push rod can be moved off the valve lifter seat and tied or otherwise held away from lifter.*

Remove lifter or lifters. If more than one lifter is to be replaced, be sure to identify them (push rods as well) so they will be installed in the same position.

Disassemble

With a suitable tool, pry out the plunger retainer ring, Fig. 11. Clean varnish deposits from inside the lifter body above the push rod seat. Then invert the lifter body and drop out the parts.

Assemble & Install

Rinse all parts in clean kerosene and assemble without drying. This will avoid the adherence of dust or lint if they are blown off or wiped with cloth.

Place the parts in the body in the order shown in Fig. 11. The plunger must slide freely in the body. Place the push rod seat on the plunger and depress these parts and install the plunger retainer in the groove in the body.

Install lifters in the reverse order of removal and on 1955 engines be sure to adjust the rocker arm nuts as directed under Valve Clearance, Adjust.

TIMING CHAIN COVER

1959-62

1. Drain cooling system.
2. Remove generator adjusting strap.
3. Remove fan and accessory drive belts.
4. Remove fan and pulley.
5. Disconnect radiator hoses.
6. Remove water inlet elbows from cylinder heads (leave attached to hose).
7. Remove fuel pump.
8. Remove vibration damper.
9. Remove front four oil pan-to-timing chain cover screws, Fig. 12.
10. Remove cover attaching screws.
11. Pull cover forward to clear studs and remove.

Fig. 12 Front of engine with timing chain cover removed

1955-58

1. Drain radiator.
2. On cars with power steering, remove pump with mounting bracket from pad on top of timing chain cover and lay back on fender skirt where it will be out of the way. Before doing so, however, disconnect battery ground strap to prevent pump from grounding "BAT" terminal of regulator.
3. Remove generator.
4. Remove fan belt and power steering pump belt.
5. Remove fan and pulley.
6. Disconnect upper radiator hose from radiator and remove fan shroud (1955-57).
7. Disconnect lower radiator hose and heater hose and take off radiator.
8. Remove water inlet elbows from cylinder heads (leave attached to hose).
9. Remove fuel pump.
10. Remove harmonic balancer.
11. Take weight off engine front insulator, using suitable engine lifting equipment. *Do not use jack under engine oil pan.*
12. Unfasten front engine support from timing chain cover.
13. Remove front four oil pan to timing chain cover screws.
14. Unfasten timing chain cover from block and remove cover.

TIMING CHAIN

Take off radiator and timing chain cover as outlined above. Remove fuel pump eccentric and cover oil seal, Fig. 15. Align timing marks, Fig. 13, to simplify proper positioning of sprockets during reassembly. Slide chain and sprockets off ends of camshaft and crankshaft.

Fig. 11 Valve lifter disassembled

Install timing chain and/or sprockets, making sure timing marks on sprockets are aligned exactly on a straight line passing through the shaft centers. Then replace other parts removed.

CAMSHAFT

1. Drain radiator.
2. Remove intake manifold.
3. Remove crankcase ventilator outlet pipe.
4. Remove push rod cover.
5. Disconnect spark plug wires from plugs. Remove distributor.
6. Remove rocker arm covers.
7. Loosen rocker arm ball nuts so that rocker arms can be disengaged from push rods and turned sideways.
8. Remove push rods and hydraulic lifters. The rearmost rocker arm on the left bank cannot be removed if car is equipped with defroster unit (1955-57). Block it up with a spring-type clothes pin so it will not interfere with the camshaft as it is being withdrawn.
9. Remove radiator and timing chain cover, chain, sprockets and related parts.
10. Unfasten and remove camshaft thrust plate.
11. Slide camshaft out of engine carefully, making sure not to damage bearings in block. *The front of the engine should be raised as necessary to permit shaft to slide between the grill and hood catch plate support.*

Reverse the removal procedure to install the camshaft. Line up the timing marks on the sprockets and install the chain as shown in Fig. 13. Be sure to adjust the rocker arm ball nuts as outlined under Valve Clearance, Adjust.

Fig. 13 Valve timing marks

Fig. 14 Piston and rod assembly. 1955-56

PISTONS & RODS, REMOVE

1. Drain radiator and engine oil.
2. Remove intake manifold and cylinder head on bank from which piston is to be removed.
3. Remove oil pan and if 5, 6, 7 or 8 rod and piston is to be removed, remove oil baffle and oil pump screen.
4. Rotate crankshaft so crank pin carrying assembly to be replaced projects straight downward.
5. Remove bearing cap and push assembly up and out of block, using extreme care to see that crankshaft journal is not nicked during the process.

PISTON & ROD, ASSEMBLE

Assemble pistons and rods as indicated in Figs. 14 and 15.

PISTONS

New pistons are furnished in standard size and .005", .010", .020" and .030" oversizes. Since these are nominal or basic sizes it is important that new pistons be measured to insure proper fit. All new pistons are provided with selectively fitted piston pins, therefore, it is important to check the fit of the pin in connecting rod bushings.

If the equipment required to measure fit of pistons in cylinder is not available, a fit can be satisfactorily checked by using a ½" x .0015" feeler ribbon and spring scale. When fitting pistons to cylinders by this method, the fit should be checked with the piston in the lower half of the cylinder, and both cylinder wall and piston clean and dry. The feeler ribbon should require a pull (in pounds listed in the chart) when drawn from between the piston (without rings) and cylinder wall.

If the pistons are to be reused with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an old piston ring, filing the broken end to a sharp, square edge and using it to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material.

Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Rinse the piston in solvent and wipe off the carbon on the sides of the piston. *Never use a wire brush to clean a piston* as the brush will round off the edges of the ring lands. Pistons showing scuffed or scored skirts should be scrapped. Examine the ring lands carefully for cracks. If the piston is in the least bit doubtful, it should be discarded.

PISTON PINS

1958-62

Piston pins are pressed into the connecting rods instead of being retained by snap rings as in the past. Therefore, when necessary to install new pins suitable press equipment should be used. Fitting the pin in the piston is the same as outlined for earlier models.

1955-57

The fit of piston pin should be checked in the piston and also in the rod bushing. When new pistons (with pins), oversize pins, or new rod bushings are installed, honing of bushing or piston pin bosses, or both, may be necessary to effect a proper fit.

The fit of the piston pin in the rod bushing should be .0003" to .0005" loose (.0001" to .0006" on 1956-57).

Fig. 15 Piston and rod assembly. 1957-62

Fig. 16 Checking bearing clearance with Plastigage

Pin and bushing should be dry when checking this fit. If clearance is excessive, as determined by micrometer measurement of inside diameter of bushing and outside diameter of pin, new bushing or oversize pin should be installed.

The piston fit in the piston is zero to .0002″ loose (zero to .0004″ on 1956-57) with pin and piston bosses clean and dry. When clearance is toward the high limit pin can be inserted by light hand pressure (pin should not fall through by its own weight).

When clearance is toward the low limit (zero) considerable hand pressure will be required to insert the pin. By using a brass drift, pin can be tapped into place with light pressure. Piston and pin must be at room temperature when checking fit.

PISTON RINGS

When new piston rings are installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gaps of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with the lower end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of rings carefully with a smooth file.

ROD BEARINGS

Connecting rod bearings can be replaced without removing the rod assembly by removing the cap and replacing the upper and lower bearing halves. The clearance between the bearing and crankshaft can be measured with Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft and bearing.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the cap.
3. Reinstall cap and tighten to the torque value given in the *Engine Tightening Specifications* table.
4. Remove the bearing cap and determine bearing clearance by comparing the width of the flattened Plastigage with the graduation on the Plastigage envelope, Fig. 16. The number within the graduation on the envelope indicates the clearance in thousandths of an inch. If clearance is excessive, replace the bearing.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To Install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Torque Specifications* table.

CRANKSHAFT OIL SEAL

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool, Fig. 17. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜″ from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

OIL PAN REPLACE

1961-62

1. Drain radiator and oil pan.
2. Remove hood and air cleaner.

Fig. 17 Installing rear main bearing oil seal

3. Disconnect battery ground cable.
4. Remove upper radiator support and fan guard.
5. Unfasten and move coil away from body.
6. Remove crossover and exhaust pipe-to-exhaust manifold retaining nuts.
7. Unfasten and lower idler arm and tie rod.
8. Remove front engine mount bolts.
9. Unfasten and lower starter motor.
10. Remove oil pan bolts.
11. Remove clutch housing lower cover.
12. Hook chain fall under front of intake manifold and lift engine as high as possible.
13. Let oil pan drop.
14. Remove front main bearing cap and move crankshaft to No. 1 "up" position.
15. Holding crossover pipe and tie rod down, remove oil pan.
16. Reverse removal procedure to install pan.

1960

1. Remove engine fan.
2. Drain radiator just enough to allow removal of upper and lower radiator hoses.
3. Raise front of car and place on jack stands.
4. Drain oil from crankcase.
5. Disconnect crossover pipe at left hand exhaust manifold and at right hand exhaust connector. Remove crossover pipe. Disconnect exhaust pipe from right hand exhaust manifold. If equipped with dual exhausts, disconnect both exhaust pipes from exhaust manifolds.
6. Remove two rear oil pan screws which retain flywheel housing front shield-to-cylinder block. Remove two screws which retain shield to flywheel housing and remove shield.
7. Remove flywheel housing lower cover.
8. Disconnect clutch linkage (if equipped).
9. Remove frame bolts from right hand idler arm bracket.
10. *Remove* front engine mount-to-frame bolts and *loosen* rear engine mount-to-frame bolts.
11. Disconnect oil cooler lines at timing cover.
12. Loosen Hydramatic oil filler tube bracket to allow clearance between tube and floor pan.
13. Jack up front of engine until sufficient clearance is obtained between oil pan and rear upper edge of engine support cross member.
14. Remove screws and oil pan.
15. Reverse above procedure to install pan.

1959

1. Remove air cleaner and fan.
2. Drain radiator to allow removal of upper radiator hose on cars with air suspension.
3. Remove exhaust crossover pipe.
4. Disconnect exhaust pipe from right-hand exhaust manifold.
5. If equipped with dual exhaust system, disconnect exhaust pipes from manifolds.
6. Remove flywheel housing front shield (6 screws).
7. Remove crankcase outlet ventilator pipe (or cleaner if equipped).
8. Remove flywheel housing lower cover.
9. Disconnect clutch linkage (if equipped).
10. Remove frame bolts from right-hand idler arm bracket.
11. Remove front and rear engine mount bolts.
12. Loosen Hydra-Matic oil filler tube bracket to allow for clearance between tube and floor pan.
13. Place jacks beneath bell housing and raise engine until about 4" clearance is obtained between oil pan and rear upper edge of engine support cross-member.
14. Remove oil pan.
15. Reverse above procedure to install pan. Be sure no distortion is injected into engine mounts during installation.

Fig. 18 Exploded view of oil pump

1955-58

1. Drain oil from crankcase.
2. Remove engine side pans.
3. Remove two idler lever support attaching screws and lower the steering linkage as far as possible (1955-57).
4. Disconnect exhaust crossover pipe from both manifolds and from exhaust pipe. (Universal socket must be used at left manifold connection.) Remove pipe by shifting it around to a position where it will come out without forcing.
5. Remove two rear oil pan screws which retain flywheel housing front shield to cylinder block. Remove four screws which retain shield to flywheel housing and remove shield.
6. Remove flywheel housing lower cover.
7. Loosen crankcase ventilator outlet pipe brace clamp and swing brace out of the way.
8. Remove oil pan screws and drop pan.

Reverse the removal procedure to install the pan and related parts. However, the rear main bearing cap gasket should be removed from its groove in the cap, the groove cleaned thoroughly and a new gasket installed. Apply gasket cement to the groove before installing the gasket.

OIL PUMP REPAIRS

Remove oil pan. While holding pump in place, remove attaching screws. Lower the pump away from the block with one hand while removing the oil pump drive shaft with the other.

Remove oil screen and pressure regulator parts. Detach cover from pump body and take out gears, Fig. 18.

Examine all parts for damage and assemble. Do not attempt to change oil pressure by varying length of pressure regulator spring.

Position drive shaft in distributor and oil pump drive gear. Place pump in position in the block, indexing the drive shaft with pump drive gear shaft. Install attaching screws with lock washers and tighten securely.

Removal and installation of pump does not affect distributor timing since the oil pump and distributor drive gear are mounted on the distributor shaft.

RADIATOR

1. To remove radiator, remove attaching screws which fasten fan shroud (if equipped) to radiator and move shroud out of the way.
2. Disconnect hoses from radiator.

Fig. 19 Ignition details. 1955-56

Fig. 20 Ignition details. 1957-62

3. Unfasten radiator from support.
4. Lift radiator out of support. *If removing Hydra-Matic transmission radiator, disconnect inlet and outlet hose and plug openings with cork or similar plug.*
5. Install radiator by reversing removal steps and, after refilling radiator, run engine and check for leaks. *If Hydra-Matic radiator, recheck transmission oil level.*

WATER PUMP, REPLACE

Water pump is serviced only as an assembly. To remove, drain radiator and engine block. Remove fan belt, fan and pulley. Unfasten pump from block and lift off.

Install the pump in the reverse order. When pump is installed, drain hole will be at the bottom.

WATER DISTRIBUTOR TUBE

A water distributor tube (inlet tube) is located in each cylinder head. Whenever a valve job is being done, these tubes should be pulled out and examined. If damage or corroded, install new tubes.

DISTRIBUTOR, REPLACE

1. Disconnect distributor-to-coil primary wire.
2. Remove distributor cap.
3. Crank engine so rotor is in position to fire No. 1 cylinder and timing mark on vibration damper is indexed with pointer.
4. Remove vacuum line from distributor.
5. Remove distributor clamp.
6. Lift distributor from engine.

Installation

1. Check to see that engine is at firing position for No. 1 cylinder.
2. Install new gasket on block.
3. Install distributor so vacuum unit faces right side of engine and rotor points toward contact in cap for No. 1 cylinder.
4. Install distributor clamp, leaving screw loose enough to allow distributor to be turned for adjustment.
5. Attach vacuum line to distributor.
6. Install wires in distributor cap, Figs. 19 and 20.
7. Attach distributor primary wire.
8. Adjust point gap, replace cap and set ignition timing.

IGNITION TIMING

With the breaker gap set to the proper clearance, crank the engine to bring No. 1 piston up on its compression stroke and stop when the ignition mark on the vibration damper is in line with the pointer.

Locate No. 1 spark plug wire on the distributor cap, Figs. 19 and 20, place the cap in position on the distributor and mark the housing opposite No. 1 terminal so that its relative position will be known when the cap is removed.

Loosen the distributor body clamp and rotate the distributor until the points close. Then rotate the distributor in the opposite direction until the points just begin to open, after which tighten the clamp bolt.

For best results, use a timing light to check the timing, and be sure to disconnect the vacuum line to prevent the advance mechanism from functioning.

STARTER REPLACE

1. Disconnect battery-to-starter cable from battery post.
2. Remove rubber cover from junction block on left fender skirt.
3. Disconnect junction block-to-solenoid wires from junction block.
4. Remove battery cable from clip on junction block.
5. Remove engine side apron from below starter.
6. Pull battery cable and solenoid wire loom down so they hang free.
7. Unfasten and remove starter from flywheel housing.

If clearance is insufficient to drop starter, look for worn engine mounts. If worn, remove transmission crossmember to get out starter.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck either in the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Move the valve up and down a few times to work in the oil. *Never use engine oil for this purpose as it will leave a residue which hampers valve operation.*

Engine Stumble On Acceleration

1959-60 Carter AFB Carbs.—This condition is caused by a collapsed accelerator pump "S" link which connects the pump lever and pump plunger. This collapse, caused by improper hardening of the part, shortens the pump stroke, resulting in this condition. A new link should be installed with particular caution that the lower end of the link points toward the carburetor air horn. If installed incorrectly, it will contact the bowl cover casting during operation.

1960 Two-Barrel Carbs.—This condition is caused by improper positioning of the air cleaner assembly. Position the air cleaner inlet tube 30° to 40° to the right of the engine centerline, except on air conditioned cars where the generator limits the amount of rotation.

Choke Sticking

1960 Rochester 2GC—In most instances this condition is caused by a burr at the upper end of the fast idle link. This condition may be aggravated by a burr around the pierced hole for the link in the fast idle lever. In a few cases the condition has also been caused by a roughness or out-of-round condition at the lower end of the link causing a bind at the fast idle cam.

Corrective measures are to remove the fast idle link and lever and smooth out the areas mentioned, using a small flat file.

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter.*

CARTER NOTES

IDLE SPEED SETTING

1958-62 4-barrel carburetors do not have a conventional throttle speed screw but instead use an air adjustment screw. The idle air screw is located in the throttle body and can be identified by it being larger than the idle mixture screws. Turning the air screw outward increases engine speeds but also leans the mixture. This must be compensated for by adjusting the idle mixture screws.

METERING ROD

WCFB, WCD and WGD—Metering rod adjustment must be made after pump adjustment. With throttle valves seated, loosen metering rod arm clamp screw. With metering rods in place, press down on vacumeter link until rods bottom in casting. Holding rods down, revolve metering rod arm until finger on arm contacts lip of vacumeter link. Hold in place and tighten clamp screw.

Fig. ①—AFB float level. Adjust by bending float lever.

Fig. ②—AFB float drop. Adjust by bending stop tabs on float brackets.

Fig. ③—With pump connector link installed with offset toward pump lever, there should be the dimension specified from top of bowl cover to top of plunger shaft. Adjust by bending throttle connector rod.

④—With engine at normal operating temperature and with fast idle screw on highest step on fast idle cam, turn screw to obtain the specified rpm.

Fig. ⑤—With throttle valve wide open there should be the clearance specified between upper edge of choke valve and inner wall of air horn. Adjust by bending unloader lip on throttle shaft lever.

Fig. ⑥—WCFB and WCD float level. Adjust by bending float lever.

Fig. ⑦—WCFB float drop. Adjust by bending stop tabs on float bracket.

Fig. ⑨—WGD float lever. Adjust by bending float lever.

Fig. ⑩—with pump connector link in outer hole of pump arm, flat on pump arm should be parallel with a straightedge placed across dust cover boss. Adjust by bending throttle connector rod.

⑪—See ⑩. With throttle valve closed, flat on pump arm should be parallel with a straightedge placed across dust cover boss. Adjust by bending pump arm.

⑫—After adjusting fast idle speed, shut off engine. Then with fast idle screw resting on highest step of fast idle cam, clearance between dashpot plunger screw and throttle lever should be as specified. Adjust plunger screw as required.

⑬—With throttle valve wide open, there should be the clearance specified between upper edge of choke valve and inner wall of air horn. Adjust by bending choke shaft unloader arm.

ROCHESTER NOTES

IDLE SPEED SETTING

Some 1958-62 carburetors do not have a conventional throttle speed screw but instead use an air adjustment screw. The idle air screw is located in the throttle body and can be identified by it being larger than the idle mixture screws. Turning the air screw outward increases engine speeds but also leans the mixture. This must be compensated for by adjusting the idle mixture screws.

HOT IDLE COMPENSATOR

All 1962 two-barrel carburetors with automatic transmission and air conditioning have a hot idle compensator. During idle adjustment, make sure that hot idle compensator is closed by depressing the spring-loaded button.

①—After adjusting fast idle speed, shut off engine. Then with fast idle screw resting on highest step of fast idle cam, clearance between dashpot plunger screw and throttle lever should be as specified. Adjust plunger screw as required.

③—Bend unloader tang on fast idle cam to obtain clearance specified between choke valve edge and dividing wall of air horn with throttle valves wide open.

Fig. ②—With throttle valves closed, bend pump arm as necessary to obtain specified measurement from top of air horn casting to top of pump rod.

Fig. ④—2GC float level.

Fig. ⑤—2GC float drop.

ROCHESTER NOTES
continued

Fig. ⑲—Idle vent valve adjustment.

Clutch and Transmission Section

CLUTCH PEDAL, ADJUST

1955-57

Clutch pedal free play should be adjusted at the clutch fork-to-countershaft rod from ¾″ to 1⅛″.

1958

1. Set clutch pedal stop bracket (under instrument panel) to provide the correct pedal height of 5½″ to 5¾″ above floor mat.
2. Disconnect clutch pedal push rod at junction with linkage (remove clevis pin).
3. With pedal held up tight against stop bracket, adjust clevis at lower end of pedal push rod until clevis pin will enter freely.
4. Then adjust the clutch fork rod until ½″ to ⅝″ free pedal play is obtained.

1959

Clutch pedal free travel should be approximately ⅝″ and pedal height should be adjusted to 6¾″ to 7″ above the floor mat.

To adjust free pedal travel, remove all free pedal travel with the adjusting nut; then back off 3½ to 3¾ turns.

To adjust pedal height, loosen pedal rod upper trunnion jam nuts. Adjust pedal height and tighten jam nuts 5 to 10 ft. lbs. torque.

1960

Clutch free pedal travel should be approximately ¾″ and pedal height should be adjusted to 6½″ above floor mat.

To adjust free travel, loosen clutch fork rod adjusting lock nut. Remove all free travel with adjusting nut, then back off 3½ turns.

To adjust pedal height, loosen pedal rod upper trunnion jam nuts and adjust pedal height.

1961-62

1. Loosen clutch fork rod adjusting lock nut.
2. Adjust silencer bumper so that countershaft is lifted .015 to .020″ off stop.
3. Remove clutch fork lash with adjusting nut, then back off adjusting nut 4½ turns (5 on 1961) on a new clutch driven plate installation or 3½ turns when worn or old clutch driven plate is reinstalled.
4. Tighten lock nut to 60-120 inch lbs.
5. Pedal height should be 6¾ to 7″ (6-6¼″ on 1961) above floor mat. If adjustment is required, loosen pedal rod upper trunnion jam nuts and adjust. Tighten jam nuts to a torque of 60-120 inch lbs.

CLUTCH SERVICE

1961-62

1. To remove clutch, disconnect positive cable at battery.
2. Remove transmission.
3. Remove clutch release bearing through rear opening in clutch housing (do not immerse bearing in any cleaning solvent).
4. Remove clutch fork rod.
5. Disengage pedal push rod from countershaft.
6. Rotate countershaft to remove overcenter spring.
7. Screw out left hand pivot pin from countershaft. Move left end of countershaft rearward, withdrawing right end of shaft out of bushing in flywheel housing.
8. Remove starter and front flywheel housing shield.
9. Unfasten and remove flywheel housing.
10. Mark clutch pressure plate cover and flywheel to insure reassembly in the same position as balanced at the factory.
11. Loosen clutch cover bolts one turn at a time until tension is relieved.
12. Remove all but the top bolt and move clutch away from flywheel at bottom to permit removal of clutch driven plate.
13. Remove remaining bolt to remove cover plate assembly.
14. Installation is made in the reverse order of removal. Use a spare main drive gear to align clutch disc during installation. Be sure to align marks on flywheel and clutch cover (if original clutch is being installed) to restore balance set up at factory. Tighten clutch cover-to-flywheel bolts one turn at a time until tight, then torque to 25-35 ft. lbs.

1958-60

1. To remove the clutch, remove transmission as outlined further on.
2. Remove clutch housing bottom cover.
3. Disconnect clutch fork return spring and remove clutch fork ball support and fork from housing.
4. Remove clutch release bearing.
5. Mark clutch pressure plate cover and flywheel so they can be reassembled in the same position as balanced at factory.
6. Loosen bolts holding cover to flywheel one turn at a time until tension is relieved.
7. When bolts are removed, move clutch away from flywheel at bottom so as to permit removal of clutch driven plate.
8. Lower cover and pressure plate through bottom of clutch housing.
9. Installation is made in the reverse order of removal. Use a spare main drive gear to align clutch disc during installation. Be sure to align marks on flywheel and clutch cover (if original clutch is being installed) to restore balance set up at the factory. Tighten clutch cover-to-flywheel bolts one turn at a time until tight, then torque to 30 ft. lbs.

1955-57

1. Remove transmission as outlined further on.
2. Remove clutch release bearing from release fork.
3. Remove clutch fork tension spring from fork.
4. Disconnect clutch fork push rod.
5. Remove clutch fork by forcing it

Fig. 1 Exploded view of 1955 synchromesh transmission

forward and toward center of vehicle.

6. Install a suitable clutch pilot tool or a spare clutch shaft to support clutch assembly during removal.
7. Loosen clutch attaching bolts one turn at a time until diaphragm spring is released.
8. Remove clutch pilot tool and take clutch assembly from vehicle.

Disassemble

1. Remove three drive strap-to-pressure plate bolts and retracting springs and remove pressure plate from clutch cover. *When disassembling, note position of grooves on edge of pressure plate and cover. These marks must be aligned at assembly to maintain balance.*
2. The diaphragm spring and two pivot rings are riveted to the clutch cover. Spring, rings and cover should be inspected for excessive wear or damage and if there is a defect, it is necessary to replace the complete cover assembly.

Inspection

1. Wash all parts except the release bearing in cleaning solvent. *The release bearing is permanently packed with lubricant and should not be soaked in cleaning solvent as this may dissolve the lubricant.*
2. Inspect pressure plate and flywheel for scores on contact surfaces.
3. Check drive-straps for looseness at the clutch cover rivets and evidence of looseness at pressure plate bolt holes.
4. Check release bearing for roughness and free fit on sleeve of clutch shaft bearing retainer.
5. Inspect clutch disc for worn, loose or oil soaked facings, broken springs, loose rivets or riding.
6. Examine splines in hub and make sure they slide freely on splines of clutch shaft. If splines are worn, clutch disc or clutch shaft should be replaced as necessary.

Assemble

1. Install pressure plate in cover, lining up groove on edge of pressure plate with groove on edge of cover.
2. Install pressure plate retracting springs and drive strap-to-pressure plate bolts and lockwashers. Tighten to 11 lb. ft. torque. The clutch is now ready to be installed.

Installation

1. Install clutch disc, pressure plate and cover assembly, and support them with clutch pilot tool or spare clutch shaft.
2. Turn clutch assembly until mark on cover flange lines up with mark on flywheel. Align nearest bolt holes in clutch and in flywheel.
3. Install attaching bolts and tighten each one a turn at a time to prevent distorting the cover as the spring pressure is taken up.
4. Remove clutch pilot tool.
5. Pack clutch fork ball seat with a small amount of high melting point grease.
6. Install fork on ball in clutch housing.
7. Lubricate recess on inside of release bearing collar and coat release fork groove with a small amount of graphite grease.
8. Install release bearing assembly to the fork and hook up linkage.
9. Install transmission.

TRANSMISSION, REPLACE

1958-62

1. Remove propeller shaft assembly.
2. Disconnect speedometer cable.
3. Disconnect gearshift linkage.
4. On 1961-62, support rear of engine with jack. Then remove two transmission bracket-to-crossmember retaining nuts.
5. Remove upper transmission-to-clutch housing bolts and install aligning studs in these holes.
6. Remove lower bolts and remove transmission.
7. Reverse removal procedure to install transmission.

1955-57

Before removing the transmission on 1955-57 models, the back-up lamp switch wires must be disconnected.

1. Disconnect speedometer cable, gearshift selector rod and control rod from transmission.
2. Disconnect rear universal joint, using a wire or rubber band to prevent trunnions from slipping off universal joint spider.
3. Remove propeller shaft by sliding it to the rear off the transmission mainshaft spline.
4. Remove transmission shifter lever spring yoke and extension to obtain working clearance when removing upper capscrew holding transmission to clutch housing. To avoid damage to shifter levers on shaft inside of transmission, remove shifter lever screw while holding shifter lever in neutral (center position). Then take off the shift lever.
5. Remove the transmission upper capscrews and install two transmission guide pins. These pins can be made by cutting the heads off two transmission capscrews and sawing a screwdriver slot in the ends.
6. Remove lower capscrews and move transmission to the rear.
7. Bring the rear bearing extension into

Fig. 2 Synchromesh transmission cluster gear and reverse idler gear details, 1955

the intersection of the frame "X" members until main drive gear is free.

8. Lower transmission to floor.

TRANSMISSION REPAIRS

1955, Fig. 1

1. Remove external shift parts and take off cover.
2. Unfasten rear bearing retainer and withdraw mainshaft assembly.
3. Remove internal shifter parts.
4. Drive countershaft out through rear, allowing cluster gear to lie in case.
5. Release snap ring and push main drive gear into case and lift out.
6. Remove cluster gear, Fig. 2.
7. Drive in the retaining pin, push out reverse idler shaft and lift out gear.
8. To disassemble mainshaft, expand wire retainer and slide second speed drum from shaft. Release snap ring and thrust washer and slide off second speed gear.
9. To disassemble the main drive gear, expand wire retainer and remove synchronizing drum. Release snap ring and washer and bump the shaft of a wooden block to remove bearing.

NOTE—The main drive gear shaft, Fig. 3, is undercut to accommodate the main drive gear oil seal. An oil slinger is installed next to the transmission front bearing and held in place by a spring washer and snap ring. When the transmission is installed, the oil slinger extends over the flared end of the clutch release bearing support.

Assembly Notes — When replacing the main drive gear bearing, make sure that the shielded side is placed toward the gear. Press the bearing firmly in place, using a tube placed over the gear shaft and pressing on the inner race of the bearing.

Make sure that the high and second speed clutch slides freely on the mainshaft. The synchronizing drums must be smooth and free from scores. They must also show the heaviest contact on their large diameters for best results when synchronizing. Make sure that the oil grooves are cleaned.

To assemble the countergear, insert a dummy shaft in place of the regular countershaft and insert 25 needle rollers at each end of the gear, Fig. 4, after using a liberal supply of vaseline or lubriplate to hold them in position. Coat the bearing retainers and thrust washers with lubricant and position them at each end of the cluster.

Lay the countergear assembly in the bottom of the case until the main drive gear is installed. When this has been done, position the cluster gear assembly and install the countershaft from the rear of the case, pushing the dummy shaft out through the front. Align the slots in the case and the shaft and insert the lock ball before driving the countershaft to its final position.

On models prior to 1955 installing the idler shaft pin, its outer end should be ¾" from the outside of the transmission case. On 1955, the reverse idler gear shaft is retained by a set screw which also acts as a support for the selector shaft shift lever spring support.

Fig. 3 Oil seal and slinger on synchromesh transmission main drive gear, 1955

Fig. 5 Section through 1956 transmission. The 1957 transmission is similar but a steel thrust washer has been added to the rear of the mainshaft second speed gear and is retained by a snap ring

1956-57, Fig. 5

1. Thoroughly clean all dirt from exterior of transmission to avoid getting dirt into bearings when transmission is opened.
2. Remove transmission cover and gasket, toggle spring, spring clip and spring extension.
3. Remove speedometer driven gear, then remove rear bearing retainer and gasket.
4. Place transmission in second gear, move mainshaft back until rear bearing is clear of case, and disengage shift yoke from synchronizer. Then lift front end of mainshaft enough to remove synchronizer from shaft. Note that the counterbored end of the synchronizer must face the second speed gear when replaced.
5. Remove snap ring holding second speed gear to mainshaft. Remove thrust washer after lining up small wire spacer ring installed in bottom of snap ring groove with thrust washer key, then remove second speed gear from mainshaft.
6. Remove snap ring holding low and reverse gear to mainshaft.
7. Slide low and reverse gear off mainshaft while pulling shaft out through rear of transmission case.

Fig. 4 Assembling countershaft rollers on synchromesh transmission, 1955

Fig. 6 Three speed standard manual shift transmission. 1958-62

8. Place transmission levers in neutral and remove set screws holding shifter yokes and levers to their respective shafts. *Each yoke shaft is in neutral position when the notch for the shifter lever is directly above the selector shaft.*
9. Slide shift lever and interlock away from second and high yoke shaft, then remove interlock retainer from groove in right end of selector shaft.
10. Remove outer shift lever and lock washer from left end of selector shaft and, after making sure transmission is still in neutral, depress inner selector lever and drive the shaft out through the right side of the transmission, using a soft hammer. *The welch plug in right side of case will be driven out by the shaft. Do not allow shift levers and interlock to drop into case.*
11. Push second and high speed yoke shaft out through front of case, taking care to prevent poppet ball and spring from flying out. Remove shift yoke, ball and spring.
12. Taking care to prevent poppet ball and spring from flying out, push low and reverse yoke shaft out through rear of case. Remove poppet ball, spring and low and reverse interlock pin.
13. Drive countershaft lock pin into the shaft, then drive shaft out through rear end of case, using a suitable tool to hold needle bearings and washers in place. Allow cluster gear to rest on bottom of case.
14. Remove snap ring from main drive gear bearing and tap drive gear and bearing toward rear of transmission to remove.
15. Carefully raise cluster gear out of case so that related parts remain in gear.
16. Remove transmission outer selector lever, lock washer and nut; then remove inner lever and shaft, spring washer, flat washer, and oil seal from case.
17. Drive reverse idler gear shaft lock pin into the shaft, then remove shaft, gear and thrust washers.

Assembly Notes

Reverse the order of the foregoing procedure to assemble the transmission, observing the following:

Install the reverse idler gear so that the chamfered teeth are at the rear of the case. The idler gear shaft is ground slightly larger at one end in order to form a positive seal at the rear end of the transmission case. Make sure that this end of the shaft is at the rear when replaced and that the small hole in the opposite end lines up with the lock pin hole in the case. Install a new lock pin coated with white lead or other sealing compound to prevent leaks. Drive lock pin 1″ below surface of boss on case.

When installing the cluster gear and related parts, note that a small diameter

Fig. 7 Three speed heavy duty transmission, 1958-60. For 1961-62 a long extension housing is used at rear of transmission case

bronze washer and a steel washer are used at the rear of the gear (bronze washer next to gear) and a larger bronze washer (only) is used at the front. When countershaft is installed, install a new lock pin coated with white lead or other suitable sealing compound to prevent leaks. Drive pin flush with surface of transmission case.

After shift yoke shafts are installed, install a new welch plug coated with white lead or other sealing compound in right side of transmission case.

After installing second speed gear on mainshaft and, after lining up the small wire spacer ring in bottom of mainshaft snap ring groove with spline which is machined *part way* onto the ground second speed gear bearing surface, install second speed gear thrust washer and snap ring. Note that one spline is machined the entire length of the second speed gear bearing surface on the mainshaft. This full spline is for lubrication purposes and should not be obstructed by the thrust washer key.

3 SPEED STD. TRANS.

1958-62

Disassemble, Fig. 6

1. Remove side cover and gasket.
2. Remove main drive gear bearing retainer and, with the puller remove the main drive gear and bearing.
3. Remove 24 roller rear pilot bearings, 2 washers and 14 roller front bearings.
4. Unfasten extension housing from transmission case and pull extension and mainshaft out of transmission case, leaving the synchronizer and first and reverse gear in case.
5. Remove synchronizer clutch sleeve and first and reverse gear through side opening in case.
6. Remove countershaft by driving it from front to rear of case, using a soft steel drift. Remove the countergear rollers and thrust washers.
7. Remove the countergear.
8. Drive the idler shaft lock pin into the shaft. This pin is shorter than the diameter of the shaft so the shaft may be slipped out when the pin is driven in.
9. Using a drift pin, tap rear of idler shaft to drive out plug ahead of shaft. Do not turn the shaft while removing as the lock pin may drop down between the idler gear bushings.
10. Remove reverse idler gear and thrust washers.
11. To remove the mainshaft from the extension, expand the bearing snap ring and tap the rear of the shaft with a soft hammer to bring the shaft, speedometer drive gear, second speed gear and bearing out of the extension as an assembly.

Mainshaft, Disassemble

1. Press speedometer gear off mainshaft, using suitable split plates in an arbor press.
2. Remove bearing-to-mainshaft snap ring and press bearing off shaft.
3. Remove second speed gear thrust washer, pull drive pin out of shaft and remove second speed gear.

Mainshaft, Assemble

1. Slide second speed gear on mainshaft, insert drive pin in shaft and install thrust washer against gear.
2. Install new bearing with groove in outside diameter of bearing toward second speed gear.
3. Select one of four available snap rings so end play of bearing on shaft is a maximum of .004″. This may be determined by installing successively larger rings. Use the thickest ring that will enter snap ring groove on shaft.
4. Start speedometer drive gear on shaft with chamfered inside diameter of gear toward bearing. Press gear on shaft so forward face of gear is ⅞″ from rear face of bearing.

Assembly Details

Inspect all gears for wear or damage, and see that the first and reverse sliding gear and the clutch sleeve slide freely on the mainshaft. See that the synchro-

Fig. 8 Four speed manual shift transmission 1960-62

nizing cones are not loose in the clutch sleeve. If the cones are damaged, it will be necessary to replace the clutch sleeve assembly and both synchronizing rings.

See that the synchronizer rings are smooth and that they do not rock in the cones. Excessive rocking affects proper synchronizing of the gears during shifting.

Normally, it should not be necessary to replace the energizing springs. However, should this be necessary, the spring is assembled in its groove with its offset end between the fourth and fifth clutch teeth of either bank of teeth. This will prevent the spring from turning in its groove.

Check the countershaft bushings for excessive wear by using a narrow feeler gauge between the shaft and the bushings. The proper clearance should be from .002″ to .004″.

When installing the reverse idler, the chamfered teeth should be placed to the rear of the case. Install the idler shaft, making sure that the lock pin hole in the shaft lines up with the hole in the case at the same angle. It is well to line up these holes with a punch before installing the lock pin. Use a new lock pin and drive it in about $\frac{1}{16}$″ beyond flush with the case, and peen the hole slightly.

When installing the countershaft, the step on the forward end should be flush with the front face of the case, or about $\frac{1}{64}$″ below the face, to maintain proper transmission alignment.

When installing the mainshaft, the proper seating of the shoulder on the shaft against the inner race of the mainshaft rear bearing should permit .010″ end play of the second speed gear.

When the assembly has been completed, check the transmission in all gears to be sure that there is no indication of binding in any position.

3 SPEED HEAVY DUTY TRANS.

1958-62, Fig. 7

1. To disassemble, remove side cover.
2. On 1961-62, remove clamp, bracket and insulator from rear extension. Unfasten and move extension away from case about ½″ to expose countershaft and lock key.
3. On 1958-60, remove mainshaft nut, yoke, speedometer drive gear and spacer. Unfasten and move rear bearing retainer away from transmission about ½″ to expose countershaft and lock key.
4. On all models, from front of case, drive countershaft to rear. When lock key in countershaft clears case, remove key to permit countershaft to clear rear bearing retainer. Drive countershaft all the way out.
5. Allow countershaft gear to drop into case and then remove rear bearing retainer or extension housing, and mainshaft assembly from case.
6. Remove pilot rollers from inside main drive gear and bearing spacing washer from front end of mainshaft.
7. Remove main drive gear bearing retainer. Remove bearing snap ring and washer from main drive gear. Drive main drive gear out of bearing. Then tap main drive gear out through front of case.
8. Remove reverse idler gear.
9. Lift out countershaft gear and related parts.
10. Remove synchronizer from mainshaft and strip parts from mainshaft.

Assemble

1. Position reverse idler gear in case with chamfered teeth ends toward front and install shaft from rear of case, aligning keyway for installation.
2. Assemble parts in countershaft gear. Place small amount of grease on thrust washers to hold them in place during installation. Install tang on front thrust washer to fit into slot in case thrust face. The tab on rear

steel washer must be up.
3. Install main drive gear bearing and snap ring in case from front until snap ring bottoms on case.
4. Install drive gear retainer without a gasket and finger tighten retainer bolts. Install oil slinger on drive gear shaft with small amount of grease with dished side away from pinion bearing.
5. Install main drive gear with oil slinger in case and drive shaft into bearing.
6. Remove drive gear bearing retainer and install spacer washer and thickest snap ring that will fit.
7. Tap pinion shaft and bearing forward out of case as far as gear will allow. Install pilot rollers in drive gear pocket, using grease to hold rollers in place.
8. Install synchronizer stop ring on rear end of drive pinion shaft. Coat inside of stop ring with grease.
9. Press rear bearing on mainshaft. Install snap ring into rear bearing retainer or extension housing and tap mainshaft and bearing into retainer.
10. Assemble parts on mainshaft and install assembly in case.
11. Tap main drive gear to rear until snap ring seats on case.
12. Turn transmission to help align countershaft and install countershaft. When countershaft end is close to case, install lock key and drive into case.
13. Turn rear bearing retainer into position and bolt securely.
14. Check clearance between main drive gear bearing retainer and case. Then select gasket or gaskets that will seal lubricant and prevent end play between bearing snap ring and retainer.
15. Complete assembly and shift transmission into neutral and install side cover.

FOUR SPEED TRANS.

1960-62, Fig. 8

1. To disassemble, remove side cover.
2. Remove front bearing retainer.
3. Drive lock pin from bottom side of reverse shifter lever boss and pull shifter out about ⅛″. This disengages reverse shift fork from reverse gear.
4. Unfasten case extension from rear bearing retainer (5 bolts). Tap extension to rear. When reverse idler shaft is out as far as it will go, move extension to left so reverse fork clears reverse gear and remove extension.
5. Remove snap ring from end of mainshaft. Remove speedometer gear, reverse idler gear, tanged thrust washer and reverse gear.
6. Remove self-locking bolt attaching rear bearing retainer to case. Then remove mainshaft assembly.
7. Lift front reverse idler gear and thrust washer fom case.
8. Remove pilot rollers from main drive gear and 4th speed synchronizing ring.
9. Remove main drive gear snap ring and spacer washer. Tap drive gear from front bearing. From inside case, tap out front bearing and snap ring.
10. From front of case, tap out countershaft and remove countershaft gear and thrust washers.
11. Strip mainshaft of all parts.

Assemble

Mainshaft

1. From rear of mainshaft, assemble 1st-2nd clutch to mainshaft with sleeve taper toward rear and hub to front. Press 1st gear bushing on shaft.
2. Install 1st gear synchronizing ring so notches in ring correspond to keys in hub.
3. Install 1st gear with hub to front, and thrust washer. Make sure that grooves in washer are facing 1st gear.
4. Press rear bearing with snap ring groove toward front, making certain bearing is firmly seated against shoulder on mainshaft.
5. Choose correct selective fit snap ring and install it in mainshaft groove behind rear bearing. Snap rings are available in three thicknesses; use ring that will produce from zero to .005″ clearance between rear face of bearing and front face of snap ring.
6. From front of mainshaft, install 2nd gear synchronizing ring so notches in ring correspond to keys in hub. Install 2nd speed gear with hub toward rear, and install 2nd-3rd gear thrust (bearing) washer.
7. Install 3rd gear with hub to front and 3rd gear synchronizing ring with notches to front.
8. Install 3rd-4th gear clutch (hub and sliding sleeve) with taper toward front, making sure that keys in hub correspond to notches in 3rd gear synchronizing ring. Install snap ring in mainshaft groove in front of clutch.
9. Install rear bearing retainer plate. Spread snap ring on plate to allow it to drop around rear bearing and press on end of mainshaft until snap ring engages groove in rear bearing.
10. Install reverse gear with shift collar to rear.
12. Press speedometer gear on mainshaft so it is 4½″ from center of gear to flat surface of rear bearing retainer. Install snap ring in groove at rear of mainshaft.

Countershaft Gear

1. Install spacer in countergear.
2. Using grease to retain rollers, install 20 rollers in each end of gear, two .050″ spacers, 20 more rollers, then one .050″ spacer. Insert dummy shaft to hold parts in place during installation.

Transmission, Assemble

1. Place countershaft tanged thrust washers in place, retaining them with grease and being sure that tangs are resting in notches in case. Set counter gear in bottom of case.
2. Press bearing onto main drive gear with snap ring groove to front and firmly seat bearing against shoulder of main drive gear.
3. Install spacer washer and selective fit snap ring in groove on gear stem. Use ring that will provide zero to .005″ clearance between rear face of snap ring and front face of spacer washer.
4. Install main drive gear through side cover opening. Place snap ring in groove in front bearing.
5. With transmission resting on its front face, move countergear into mesh with main drive gear, being sure thrust washers are in place. Install key in end of countershaft and, from front of case, tap shaft until its end is flush with rear of case and dummy shaft is displaced. End play of countergear should be not more than .025″.
6. Install 14 pilot rollers in main drive gear pocket, using grease to hold them in place.
7. Place a greased gasket on front face of rear bearing retainer.
8. Install 4th gear synchronizing ring on main drive gear with clutch key notches toward rear.
9. Position reverse idler gear thrust washer (untanged) on machined face of ear cast in case for reverse idler shaft. Position front reverse idler gear on top of thrust washer with hub facing rear of case.
10. Lower mainshaft assembly into case, making certain that notches on 4th gear synchronizing ring correspond to keys in clutch assembly.
11. Install self-locking bolt attaching rear bearing retainer to case, tightening it to 20-30 ft. lbs.
12. From rear of case, insert rear reverse idler gear, engaging splines with portion of gear within case.
13. Place greased gasket on rear face of rear bearing retainer.
14. Install remaining tanged thrust washer on reverse idler shaft, being sure tang is in notch in idler thrust face of extension case.
15. Place two clutches in neutral.
16. Full reverse shifter shaft to left side of extension and rotate shaft to bring reverse shift fork to extreme forward position in extension. Line up forward and rear reverse idler gears, being sure front thrust washer is in place.
17. Start extension into transmission case by carefully inserting reverse idler shaft through reverse idler gears. Slowly push it on shifter shaft until shift fork engages reverse gear shift collar. When fork engages, rotate shifter shaft to move reverse gear rearward, permitting extension to slide onto case.
18. Install 3 extension-to-case bolts, tightening to 35-45 ft. lbs., and 2 extension-to-retainer bolts, tightening to 20-30 ft. lbs. Use suitable sealer on lower right attaching bolt (viewed from rear).
19. Adjust reverse shifter shaft so that groove in shaft lines up with hole in boss and drive in lock pin from top of boss.
20. Install main drive gear bearing retainer and gasket, making certain oil well lines up with oil outlet hole. Install bolts with suitable sealer and tighten to 15-20 ft. lbs.
21. Install a shift fork in each clutch sleeve. With both clutches in neutral, install side cover and gasket.

Fig. 9 Four speed manual shift transmission gearshift linkage. 1960-62

Tighten cover bolts evenly to 10-20 ft. lbs. torque. Use suitable sealer when installing lower right bolt. Install shift levers.

GEARSHIFT, ADJUST

For Standard Trans.

1955-57

Proper position of the gearshift lever is obtained by means of the clevis pin and trunnion which connect the gearshift control rod and selector rod, respectively, to levers at the lower end of the steering column.

When the gearshift lever is in neutral position, clearance between the lever and steering wheel should be approximately 3½" on 1955, 3¼" on 1956-57. To adjust, hold the transmission selector rod in its rearmost position (normal position for 2nd and 3rd) and adjust the selector rod trunnion for proper gearshift lever position. Lengthen selector rod to move lever closer to steering wheel.

Neutral position of the gearshift lever should be approximately 9 degrees above horizontal (13 degrees on 1956-57). To raise or lower the lever, adjust the length of the control rod by adjusting the clevis.

1958

Proper gearshift lever position is obtained by means of the shifter levers which connect respectively to the gearshift control rods.

1. Set both lower steering column shifter levers in the neutral position and both transmission shifter levers in neutral detent position.
2. Adjust shifter rods by adjustment provided at shifter rod swivels until the shift lever at the steering wheel is approximately 13 degrees above the horizontal.

1959

With shifter levers in neutral position and transmission shifter levers in neutral detent, adjust rods by adjusting nuts as required at both sides of trunnion.

Check movement of gearshift lever in neutral. A slight readjustment may be necessary due to the weight of the upper gearshift rotating the gearshift tube through the clearances in the linkage.

1960

This adjustment must be made so that both levers are located in the true neutral position in the window of the mast jacket. A special gauge (J-8638) is available to make the adjustment properly.

Insert the gauge between 2-3 shift lever and key to place tangs of both 2-3 and 1-Rev. levers in key slots and locate both levers in neutral position in window of mast jacket. With gauge in place and transmission levers in full neutral detent, adjust 2-3 shifter rod trunnion at idler lever and 1-Rev. trunnion at transmission lever.

1961-62 Three Speed Trans.

1. Position selector lever in neutral.
2. Disconnect shift rods at transmission.
3. Line up 2nd-3rd and 1st-reverse

Fig. 10 Four speed manual shift transmission gearshift linkage adjustments. 1960-62

levers at lower end of steering column so they move freely back and forth (this is neutral position).

4. Attach shift rods to transmisssion levers and, with transmission levers in full neutral detent, adjust 2nd-3rd shifter rod trunnion at idler lever and 1st-reverse trunnion at transmission lever. Tighten lock nuts to 5-10 inch lbs.

1960-62 Four Speed Trans.

As shown in Fig. 10, a simple gauge block, locally made to the specifications indicated, will aid in making the proper adjustments. The adjustments can be made without the gauge block by having an assistant hold the manual shift lever in neutral position.

1. Referring to Figs. 9 and 10, remove move gearshift lever seal from floor pan.
2. Place transmission in neutral and, if gauge block is used, position in slot.
3. Remove clevis pin at each shift lever.
4. On each shift rod, adjust threaded clevis to permit free entry of pin into hole in transmission shift lever.
5. Connect clevises to levers.
6. Remove gauge block and check shifts. If any roughness exists, one of the clevises may require adjustment of about ½ turn. Determine the rod and clevis requiring adjustment by sighting along the slot where the gauge block was used. *If transmission is removed from car, shift linkage should be adjusted before transmission is reinstalled.*

HYDRA-MATIC DRIVE

A step-by-step pictorial service procedure is given in the *Automatic Transmission Section.* The following material covers external adjustments and removing and installing the unit.

1955-57 ADJUSTMENTS

1957 Service Note

A new throttle linkage to the carburetor and transmission improves accelerator pedal feel by the use of a throttle control cross shaft. One end of the cross shaft is mounted to a bracket on the rear of the engine and the other end is mounted to a bracket attached to the dash.

Adjustment of the throttle linkage is basically the same as in 1956. The carburetor throttle rod should be adjusted so that a gauge pin fits freely through the lever and bracket at the rear of the engine.

The accelerator pedal height is set by adjusting the intermediate rod to give not more than ¼" clearance between the end of the accelerator pedal lever and the underside of the pedal bellows.

Throttle Control Linkage

1. Loosen both nuts on throttle control transmission rod trunnion.
2. Adjust engine idle speed to the recommended rpm with engine at normal operating temperature.
3. Shut off engine and install a suitable linkage adjustment pin in lever and bracket at "A", Fig. 11.
4. With idle adjusting screw seated, adjust length of carburetor throttle rod at lock nuts so that gauge pin is free in hole "A". Leave pin installed and tighten lock nuts securely. Recheck freeness of gauge pin in holes.
5. Push throttle control transmission rod downward until the throttle control outer lever is felt to touch end of travel. *Make sure when lever is in this position that top lock nut is not touching trunnion.*
6. While holding throttle control transmission rod in this position, tighten upper and lower trunnion lock nuts. Shorten throttle control transmission rod by backing off trunnion rear nut two full turns. Tighten front trunnion nut securely.
7. Remove gauge pin from "A".
8. Loosen lock nuts on throttle control intermediate rod trunnion.
9. With carburetor in "Full Open" position, and downshift return spring fully extended, adjust throttle control intermediate rod trunnion so that accelerator pedal clears floor mat by approximately ¼" at closest point. Tighten trunnion lock nuts.

Fig. 11 Hydra-Matic control linkage. 1955-56

Selector Lever Linkage

1. Place gearshift indicator in "Drive Right" position against stop which prohibits accidental shift into low range.
2. Loosen both trunnion lock nuts and remove trunnion from outer shift lever at transmission.
3. Make sure transmission outer shift lever is in "Drive Right" position (second detent from front). On Strato-Flight Hydramatic, "Drive Right" position is third detent from the front.
4. Install trunnion (with lock nuts loose) in outer shift lever, tighten front lock nut against trunnion finger tight to remove clearance in linkage and then tighten front lock nut one complete turn to lengthen rod.
5. Tighten rear nut against trunnion.

Neutral Safety Switch

1. Place selector lever in "Drive Left".
2. Loosen switch mounting screw.
3. Adjust switch bracket to a position where starter will not operate when ignition key is turned to the start position.
4. Make certain that switch arm does not touch stop on switch bracket. Then tighten switch mounting screw.

Fig. 12 Three speed Hydra-Matic linkage. 1961-62

1958 ADJUSTMENTS

Throttle Control Linkage

1. Loosen both nuts at transmission control rod trunnion.
2. After adjusting engine idle speed, shut off engine and install a suitable gauge pin through holes in throttle control lever and bracket.
3. With idle adjusting screw seated against its stop, adjust length of carburetor throttle rod at trunnion so that gauge pin is free in hole. Leave pin installed and tighten check nut securely. Recheck freeness of gauge pin in holes.
4. Push transmission throttle control rod downward until the throttle control outer lever is felt to touch end of travel. Make sure that when lever is in this position, top lock nut is not touching trunnion.
5. While holding throttle control transmission rod in this position, tighten upper and lower trunnion lock nuts. Shorten rod by turning upper nut 1½ turns against trunnion. Tighten both nuts and remove gauge pin.

Selector Lever Linkage

1. Place shift control lever and transmission lever at P (park) position and, with outer transmission shift lever trunnion nuts backed clear of trunnion, pull shift rod down toward transmission as far as possible. While holding in this position, run trunnion upper nut down to just contact trunnion.
2. Holding shift rod, shift transmission into reverse, using upper shift lever, and observe the position of upper trunnion nut.
3. If upper nut is short of trunnion, screw upper nut down to just contact trunnion and then screw it down two additional turns to assure necessary reserve. Tighten lower nut.
4. If upper nut is contacting trunnion, count number of turns nut can be backed off and still contact trunnion. If less than two turns, turn nut down two turns against trunnion from the "just contact" position and lock lower nut. If more than two turns, turn upper nut down against trunnion from the "just contact" position to the original or starting position and lock lower nut.
5. After completing above adjustments, check transmission parking lock with car on ramp or grade for positive lock.
6. The shift indicator must not be off index more than .080" after linkage is properly adjusted.

Neutral Safety Switch

1. Place selector lever in neutral.
2. Loosen switch mounting screws.
3. Adjust neutralizer switch to index with selector lever. Starter must not operate when ignition key is turned to start position with selector lever in "Drive Left" position.
4. Test to see that engine starts when lever is in P or N position.
5. Tighten switch mounting screws.

1959-60 ADJUSTMENTS

1. Remove air cleaner.
2. Loosen both nuts at transmission throttle control rod trunnion.
3. Adjust engine idle speed to 480-500 in drive range (540-560 with air conditioning).
4. Shut off engine and install a suitable gauge pin through holes in throttle control lever and bracket. *Four-barrel units are equipped with a throttle return check. Before installing pin, it will be necessary to either remove throttle return check or install a suitable tool (J-6342-01) over return check so that it will not interfere with linkage adjustment.*
5. With throttle valves fully closed, loosen lock nut and adjust length of transmission throttle control rod so that gauge pin is free in hole. Leave pin installed and tighten lock nut securely. Recheck freeness of gauge pin in hole.
6. Push throttle control rod to transmission (T.V. rod) downward until the throttle control outer lever is felt to touch end of travel. *Make sure upper lock nut is not touching trunnion.*
7. While holding rod in this position, tighten upper and lower trunnion lock nuts finger tight. Then shorten throttle control-to-transmission rod by backing off lower trunnion nut 2½ turns and tighten upper nut securely.
8. Remove gauge pin.
9. Loosen lock nut on carburetor throttle rod.
10. Adjust carburetor throttle rod to obtain 4⅞" ($5\frac{9}{64}$" on 1960) clearance from spherical end of pedal rod to body toe pan.
11. Tighten lock nut on carburetor throttle rod securely.
12. Install air cleaner.

1961-62 ADJUSTMENTS

Throttle Linkage

1. Refer to Figs. 12 and 13. Remove air cleaner.
2. Loosen two throttle control rod trunnion nuts.
3. Adjust engine idle speed to 480-500 rpm in Drive (540-560 with air conditioning).
4. Shut off engine and install a suitable pin through holes in throttle control lever and bracket. *Four barrel carburetors are equipped with an anti-stall dashpot (throttle return check). Before installing pin, either remove dashpot or install tool J-6324-01 over dashpot so that it will not interfere with linkage adjustment.*
5. With throttle valves fully closed, loosen lock nut and adjust length of transmission control rod to carburetor so that gauge pin is free in holes. Leave pin installed and tighten lock nut securely. Recheck freeness of pin in holes.
6. Push throttle valve upper control rod downward until outer throttle valve lever is felt to touch end of travel. Make sure that when lever is in this position, upper lock nut is not touching trunnion.
7. While holding throttle valve upper control in this position, tighten upper and lower trunnion lock nuts finger tight. Shorten upper control rod by backing off lower trunnion nut 2½ turns and tighten upper lock nut securely. Remove gauge pin.
8. Loosen lock nut on carburetor throttle rod. Then adjust this rod to obtain 4.55" clearance from underside of attaching boss on pedal-to-

body toe pan, Figs. 12 and 13. (approximately 3¾" to carpet).
9. Tighten lock nut on carburetor throttle rod securely.

Selector Linkage

1. Place upper shift lever and transmission lever in Park position and, with transmission outer shift lever trunnion nuts backed clear of trunnion, pull shift rod down toward transmission as far as possible. While holding rod in this position, run trunnion upper nut down to just contact trunnion. Run lower nut up to contact trunnion and lock nuts securely.
2. After completing above adjustments, check transmission parking lock with car on ramp or grade for positive lock.
3. Place upper shift lever in Drive Right position and check indicator pointer index. If necessary to adjust, loosen check nut above ball stud, adjust index by rotating rod and lock check nut securely.

Neutralizer Switch

1. Place selector lever in Neutral.
2. Loosen switch mounting screw.
3. Adjust switch to index with selector lever. Starter must not operate when ignition key is turned to start position with selector lever in Drive Left position.
4. Test to see that engine starts when selector is in P or N position.
5. Tighten switch mounting screw securely.

Fig. 13 Four speed Hydra-Matic linkage. 1961-62

HYDRAMATIC, REPLACE

1955-57

1. Raise car on hoist, drain transmission oil pan and disconnect filler pipe.
2. Disconnect speedometer cable.
3. Remove propeller shaft.
4. Loosen exhaust pipe at crossover pipe flange. On Strato-Flight models with dual exhausts, it is necessary to remove the right hand exhaust pipe.
5. Remove flywheel housing bottom cover and on Strato-Flight, remove crankcase ventilator outlet filter.
6. Drain oil from torus cover.
7. Remove linkage from transmission.
8. Remove torus cover bolts.
9. Disconnect rear engine mounting insulators from cross member.
10. Raise engine so that rear mountings are about ½" above cross member and remove cross member.
11. Lower engine below its normal position so rear flywheel housing upper attaching bolts are accessible.
12. Support weight of transmission on a suitable jack, remove rear housing-to-front flywheel housing attaching bolts.
13. Move transmission toward rear of car and lower it to the floor.
14. Reverse the foregoing procedure to install.

1958

1. The transmission, rear flywheel housing and torus assembly are removed as a unit.
2. Remove oil level indicator.
3. Drain transmission by removing filler pipe. Torus assembly can be drained at this time or it can be drained after transmission is removed.
4. Remove propeller shaft and disconnect speedometer cable.
5. Remove flywheel housing bottom cover and crankcase ventilator outlet filter.
6. If equipped with dual exhaust, right-hand exhaust pipe must be removed.
7. Disconnect rear engine insulators from engine rear support cross member.
8. Raise rear of engine until insulators are about ½" above cross member.
9. Loosen transmission filler pipe to cylinder head clamp.
10. Remove shift levers from transmission.
11. Remove engine rear support cross member.
12. Remove nuts from six torus cover-to-flywheel plate bolts.
13. Lower engine about 1½" below its normal position.
14. Disconnect cooler lines from transmission. Plug holes in transmission with corks to stop oil flow.
15. Raise transmission slightly to take weight off flywheel housing screws.
16. Remove flywheel housing screws and work transmission rearward and down out of car.

1959-60

1. Remove oil level dipstick and drain transmission.
2. Disconnect oil cooler adapter with lines and plug in adapter and transmission with corks to stop oil flow.
3. On single exhaust cars, remove exhaust cross-over pipe.
4. Remove propeller shaft and disconnect speedometer cable.
5. Remove flywheel housing bottom cover and crankcase ventilator outlet filter.
6. Disconnect shift levers at transmission.
7. Support rear end of engine and remove nuts from torus cover-to-flywheel plate bolts.
8. Support transmission with jack and remove transmission cross member and insulator assembly from frame.
9. Raise transmission slightly and remove flywheel housing bolts.
10. Work transmission rearward and out of chassis.

1961-62 3 and 4 Speed Units

1. Remove filler tube and drain transmission.
2. Remove propeller shaft and disconnect speedometer cable.
3. Remove linkage from transmission.
4. Remove parking brake guide hook from crossmember.
5. Remove oil cooler lines.
6. Loosen exhaust pipe-to-manifold nuts about ¼".
7. Remove starter motor.
8. Remove cover from bottom of case.
9. Remove flywheel front cover plate.
10. Support transmission with jack.
11. Remove crossmember.
12. Remove breather pipe.
13. Unfasten transmission from engine.
14. Remove transmission from car.
15. Reverse removal procedure to install transmission. Add fluid and adjust linkage.

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

Fig. 1 Rear axle, 1955-56

REAR AXLE, 1955-56

In this axle, Fig. 1, the splined companion flange is fastened to the pinion stem with a special nut which seats directly on a counterbore in the flange. The nut is retained by staking the end of the pinion stem into two slots milled on top of the nut.

The drive pinion is mounted on preloaded taper roller bearings. Adjustment of the pinion along its axis is obtained by shims placed between the rear bearing outer race and a shoulder in the carrier. Adjustment of preload of the two bearings is obtained by tightening the companion flange nut which compresses a sleeve over the pinion stem between the bearings. Both bearing outer races are pressed into the carrier, the rear race against pinion adjusting shims, the front race against the shoulder in the carrier. The rear bearing inner race is pressed onto the pinion stem to a shoulder at the pinion end. The front bearing is a light press to a close sliding fit on the pinion stem.

The threaded nut type of differential bearing adjustment is used. The procedure for making this adjustment, as well as the assembly of the differential case, replacing a ring gear, checking ring gear and pinion backlash and other differential case operations, is given in the *Rear Axle Chapter.*

Pinion & Bearings, Replace—After removing the differential unit from the carrier, unscrew the pinion flange retaining nut and pull off the flange. Press the pinion out of the front bearing and through the rear end of the carrier. The rear bearing cone and bearing spacer will come out with the pinion. The bearings may then be removed and installed with suitable pulling equipment.

Reverse the operations to assemble and, after pressing on the pinion flange, slip on the washer and nut. Tighten the nut until the bearings have a preload drag of 27 to 37 inch pounds on new bearings or 10 to 12 inch pounds on used bearings to rotate the pinion shaft.

To adjust the preload, draw up the nut until the spacer starts to buckle. Check the pull as shown in Figs. 2 and 3, depending upon the equipment available. This adjustment must be made every time the flange nut is removed or loosened. If the adjustment is to be made with the differential unit in the carrier, the rear wheels must be jacked off the floor.

Fig. 2 Measuring pinion bearing preload with torque wrench, 1955-56

Fig. 3 Measuring pinion bearing preload with spring scale, 1955-56

Fig. 4 Rear axle assembly. 1957-62

The pinion can be moved in toward the center of the axle by removing the required thickness of shims from between the spacer and the carrier. If it is to be moved away from the center of the axle, add shims.

Note—A new spacer is required between the pinion bearings when a new ring gear and pinion set is installed, either outer or inner members of either pinion bearing is changed, a new carrier casting used, or pinion adjusting shim thickness is increased. When the same pinion flange is removed and reinstalled as when an oil seal is replaced, checking for pinion bearing preload with a torque wrench is not necessary if care is taken to tighten the nut exactly its previous position. Should a new pinion flange be required, a torque wrench reading should be taken before loosening the nut and the nut tightened to the same torque wrench reading.

1957-62 REAR AXLE

In this type axle, Fig. 4, the differential carrier is larger and heavier to withstand the increased engine torque without excessive deflecting or twisting. The number of splines have been increased on side gears, axle shafts and drive pinion. The drive pinion and ring gear, pinion bearings, side bearings, side gears and differential case are larger. The pinion adjusting shims are located between the pinion head and the inner bearing race instead of in front of the outer bearing race on 1956. The differential pinion cross shaft is locked in the case by means of a screw and washer instead of a roll pin used in 1956. The carrier attaching screws are pressed into the axle housing and the carrier is attached to the housing screws by means of nuts and lockwashers.

Service Procedures

All service procedures are the same as in 1956. Due to the new construction, however, a new set of pinion adjusting shims is required. Shims are available in thicknesses of .004", .005", .006", .007" and .010". The pinion rear bearing must be removed from the pinion to change the shim pack. The thickness of the shim pack must be established by the red (or white) lead test as outlined in the *Rear Axles* chapter.

AXLE SHAFTS

Remove wheel and brake drum. Remove nuts from the four bolts attaching the brake backing plates to the housing. Withdraw the shaft. Before replacing, examine the oil seals and renew if damaged. Slide the shaft into place and take care not to injure the oil seals. The shaft with the left hand wheel studs goes to the left side of the car. Enter the splines of the shaft into the splines in the differential side gear and slide the shaft home, seating the shaft bearing to the shoulder in the housing. Clean the surfaces at the backing plate and oil guard and coat these surfaces with liquid seal and install a new gasket. Install the static ground brush. Tighten the bearing retainer bolt nuts. Replace the brake drum and wheel.

POWER BRAKE UNIT, REPLACE

1955-58

1. Disconnect vacuum hose from pipe running from tee connector.
2. On 1956 models, raise car and remove engine side apron from left side.
3. Disconnect hydraulic pipe from outlet fitting on hydraulic cylinder.
4. Disconnect push rod from pedal, and wires from stop light switch.
5. Remove nuts from U-bolt which retains pedal pivot bracket to steering column. Then remove pedal and bracket, with stop light switch attached.
6. Remove accelerator pedal on 1956 models.
7. Remove clutch pedal seal retainer (synchromesh cars) and steering column seal retainer and remove seals.
8. On Hydra-Matic cars, remove mounting plate and power brake unit as an assembly from floor plate.
9. On synchromesh cars, remove screws which retain power brake unit to mounting plate (brake unit will rest on frame). Remove mounting plate from floor pan. Remove power brake unit. *Do not support or carry brake unit by push rod since push rod may be pulled out of plunger.*
10. Install in the reverse order and bleed the system in the usual manner.

1959-61

1. Remove lock nut or clevis from auxiliary push rod inside car.
2. Disconnect vacuum hose from vacuum exhaust tube and cover to prevent entrance of dirt.
3. Disconnect pipe from master cylinder hydraulic port and cover opening and pipe end to prevent entrance of dirt.
4. Remove power brake unit (4 nuts).
5. Remove nut and auxiliary push rod grommet from push rod.

6. Install in reverse order of removal and bleed system in usual manner.

1962

1. If master cylinder is to be removed from power cylinder, be sure to retain the selective shims located between the two units. If shims are damaged during removal they must be replaced.
2. To remove the power cylinder, disconnect vacuum hoses from reservoir and vacuum pipe at intake manifold.
3. Disconnect pipe from master cylinder hydraulic port.
4. From inside car, remove clevis pin from brake pedal. Then remove four attaching nuts and remove power cylinder.
5. Reverse removal procedure to install the unit and torque attaching nuts to 20-35 ft. lbs. Adjust pedal clevis to provide 3⅛ to 3⅜″ from floor mat to bottom of pedal pad. Adjust stop light switch as required to provide 3/16″ of plunger extending from body. Bleed brakes as necessary and fill fluid reservoir to 1″ from top of filler hole.

BRAKE MASTER CYLINDER, REPLACE

1955-62

To remove the master cylinder, disconnect the wires from the stop light switch and the brake tubes at the master cylinder connector. Remove the brake pedal-to-push rod clevis pin and disconnect the brake pedal retracting spring. Unfasten the master cylinder from its mounting and lift it off the car. Install in the reverse order.

Front End and Steering Section

CASTER & CAMBER

1958-62

Caster and camber are adjusted by shims placed between the upper pivot shafts and the frame. Both caster and camber adjustments can be made at the same time after the wheel alignment checks have been completed. In order to remove or install shim, raise car to remove weight from front wheel and loosen the pivot shaft-to-frame bolts. In changing caster and camber, the following general rules apply:

1. To decrease positive caster, add shim to front pivot shaft bolt.
2. To increase positive caster, remove shims from front pivot shaft bolt.
3. To increase camber, remove shims from both front and rear bolts.
4. To decrease camber, add shims to both front and rear bolts.

By adding or subtracting an equal amount of shims from front and rear bolts, camber will be changed without affecting caster. After the correct number of shims have been installed, torque the pivot shaft bolts to 50-65 lb. ft. on 1958 and 80-95 on 1959-61.

On 1958 models, shims are available in thicknesses of .020″, .060″ and .120″. One .020″ shim change at both bolts will change camber ⅛°, a .060″ shim ⅜°, and a .120″ shim ¾°. One .020″ shim change at the front bolt only will change caster ¼°, a .060″ shim ¾°, and a .120″ shim 1½°.

On 1959-61 models, shims are available in thicknesses of .030″, .060″ and .164″. One .030″ shim change at both bolts will change camber 1/6°, a .060″ shim ⅓°, and a .164″ shim 1°. One .030″ shim at the front or rear bolt will change caster ⅓°, a .060″ shim ¾°, and a .164″ shim about ⅞°.

1955-57

Caster adjustment must always be made before camber adjustment. To set caster, loosen the eccentric bushing clap bolt and turn eccentric bushing to give the correct caster setting at each wheel.

When correct caster setting has been obtained, tighten the clamp bolt only enough to prevent changing the adjustment and proceed with camber adjustment.

To adjust camber, again loosen the clamp bolt and turn the eccentric bushing to get the correct camber setting at each wheel. It is never necessary to turn the eccentric bushing more than ½ turn to obtain the maximum adjustment possible on the eccentric bushing.

Tighten eccentric bushing clamp bolt to 35-40 lbs. ft. torque.

TOE-IN, ADJUST

To increase toe-in, turn the right adjusting tube in the direction of wheel rotation forward and the left adjusting tube in the direction the wheels revolve when the car is going rearward. Be sure to turn both tubes an equal amount in order to maintain the correct position of the steering wheel. When the adjustment is complete, tighten all clamp screws.

WHEEL BEARINGS, ADJUST

1. Remove dust cap and check for slip fit of bearing cones on spindles. Bores for bearing cones should have a light coat of wheel bearing grease to allow cones to creep.
2. If nut turns hard on spindle, check for and remove any burrs from

Fig. 1 Front coil spring suspension. 1958-62

spindle threads and cotter pin holes or key slots in nuts.
3. With tire off ground, tighten spindle nut with an 8″ or 10″ wrench to insure parts are properly seated.
4. Back off nut finger loose. Then tighten finger tight.
5. Tighten nut with wrench until next slot of nut lines up with cotter pin hole in spindle and insert cotter pin.

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure the front wheel bearings are properly adjusted and that the control arms are tight. Then check ball joints as follows:

To check lower ball joint for wear, jack under the lower control arm (not under frame). Then grasp the tire at top and bottom and move it in and out. If movement at the edge of the tire exceeds ¼″, the ball joint is worn and should be replaced.

To check upper ball joint, separate the joint from the steering knuckle. Then install and tighten nut on stud. The stud is then turned in its socket with a torque wrench. A torque range of ½ to 6 lb.-ft. is permissible.

1958-62 FRONT END

A ball joint front suspension is used in which both suspension and steering action are combined. The system, Fig. 1, is comprised of an upper and lower ball joint located at the outer ends of the upper and lower control arms. These joints serve as pivot points for both the vertical motion of the wheel and the rotation of the steering knuckle. Construction of both ball joints is similar except that tension is maintained on the upper joint by an integral pressure ring while the lower joint acquires tension from the front coil spring.

Shock Absorber, Replace

1. Raise car on hoist or jack up front end so weight of car is fully off front wheels.
2. Unfasten upper end of shock absorber from frame. *Shock absorber piston rod must not turn while loosening nuts. If necessary, use pliers or wrench to hold top of shock absorber stud mounting while removing nuts.*
3. Unfasten shock absorber at bottom and remove unit through lower control arm.
4. Install new shock absorber by reversing the above procedure. Be sure all grommets and retainers are correctly installed.

Front Spring, Replace

Front spring replacement may be accomplished by the chain hoist method or the floor jack method. Do not attempt to use floor jack method unless a good hydraulic jack with positive control over lowering a load slowly is available. The floor jack method is outlined as follows:

Fig. 2 Steering knuckle and related parts. 1955. For 1956-57 kingpin bushings are a press fit

1. Raise front of car until wheels are about 10″ above floor and place stand jacks under frame side members on each side of the car forward of radiator.
2. Place jack under lower control arm spring seat from which spring is to be removed and raise jack until it touches spring seat.
3. Remove wheel assembly.
4. Remove shock absorber.
5. Disconnect stabilizer link at lower control arm and steering arm at the rod.
6. Remove lower ball stud nut and press lower ball stud from steering knuckle.
7. Tilting steering knuckle out to clear control arm, lower jack slowly until spring is fully extended and remove spring.
8. To install spring, have jack pad under spring seat and place spring in seat on lower control arm. Top of spring is flat.
9. Raise jack gradually, checking to see that spring is correctly positioned. Raise until lower arm clears steering knuckle.
10. Lower jack slightly while guiding ball joint stud into steering knuckle.
11. Install nut on stud, install shock absorber and connect stabilizer link.

Control Arms and Bushings, Replace

The procedure for replacing these parts is the same as outlined for earlier models.

Ball Joint, Replace

With the control arm removed, chisel or drill heads of rivets retaining the ball joint to the control arm and drive out the rivets. Remove ball joint assembly. Install new ball joint, securing it with special bolts, nuts and washers supplied with new joints. Tighten nuts to 10-12 lb. ft. torque.

1955-57 FRONT END

Shock Absorber, Replace

1. Raise car on hoist, or jack up front end so weight of car is fully off front wheels.

2. Loosen and remove two nuts from bottom stud on shock absorber. Shock absorber must not turn while loosening nuts. If necessary, use pliers inserted through coils of front spring to hold shock absorber tube from turning.

3. Remove grommet retainer and grommet from lower stud.

4. Remove two nuts holding shock absorber upper bracket to frame.

5. Remove shock absorber with upper bracket upward out through hole in frame.

Spring, Replace

This operation requires use of a chain hoist and a car stand. If a chain hoist is not available the operation can be performed by using three car stands and a hydraulic floor jack. The latter method should not be attended unless the hydraulic jack has a positive control over slowly lowering a load.

Using Chain Hoist—

1. Lift car with hoist so wheels are 8 in. off floor and place a car stand under inner side of lower control arm spring pad from which spring is to be removed.
2. Lower car until it touches top of car stand. Remove wheel.
3. Remove shock absorber.
4. Disconnect stabilizer link at lower control arm.
5. Remove lower pivot pin from bushing.
6. Raise car slowly with chain hoist and remove spring.
7. When installing spring, have car elevated on chain hoist and place bottom of spring in seat on lower control arm. Top of spring may be identified since it is flattened and bottom end is not. End of coil at bottom of spring must index with hole provided in spring seat in lower control arm.
8. Lower chain hoist gradually, checking to see that spring is correctly seated top and bottom.
9. Install lower pivot pin and connect stabilizer link.
10. Install shock absorber and front wheel. Lower car, lubricate pivot pin and check wheel alignment.

Using Floor Jack—

1. Raise front end of car until wheels are about 10 in. above floor and place a car stand under frame side member on each side forward of front door hinge pillar so car will be firmly supported.
2. Place a car stand under the lower control arm of the spring which is *not* to be replaced.
3. Place floor jack under lower control arm spring seat from which spring is to be removed and raise jack until it touches spring seat.
4. Remove wheel on side of car from which spring is to be removed.
5. Remove shock absorber and disconnect stabilizer link at lower control arm.
6. Remove lower pivot pin.
7. Slowly lower jack until spring is fully extended and remove spring.
8. To install spring, have jack pad under spring seat and place spring in seat on lower control arm with end of

coil at bottom of spring indexing with hole in spring seat.

9. Raise jack gradually, checking to see that spring is correctly seated top and bottom.

10. Install lower pivot pin and connect stabilizer to lower control arm.

11. Install shock absorber and front wheel. Lower car, lubricate pivot pin and check wheel alignment.

Kingpins & Bushings, 1955

1. Jack up wheel under lower control arm and remove wheel and brake drum assembly.

2. Remove brake backing plate without disconnecting brake hose. Place backing plate out of way to avoid any strain on brake hose.

3. Remove kingpin lock pin, Fig. 2.

4. Remove lower welch plug under kingpin by driving a punch through upper welch plug. If necessary, the kingpin can then be driven up to remove upper welch plug.

5. Drive out kingpin.

6. Bushings are the floating type and may be lifted out.

7. Use a suitable reamer to clean up recesses for welch plugs in knuckle.

8. Install new bushings. No reaming or burnishing is required.

9. Position the steering knuckle on the knuckle support and install new kingpin. Make sure thrust bearing is correctly installed below knuckle support.

10. Drive in kingpin lock pin.

11. Install welch plugs in both ends of knuckle, staking them securely in place.

12. Complete the installation and lubricate kingpin.

Kingpins & Bushings, 1956-57

Procedure for removing and installing kingpins and bushings is the same as previous models except that, being a press fit, the bushings will have to be pressed in and out of the knuckle.

When installing bushings, align grease hole in bushing with similar hole in steering knuckle. Press new bushing into place with a suitable tool. After installing, line-ream bushings to size.

HORN SOUNDER & STEERING WHEEL

1961-62 Standard Wheel

1. Pry out horn button.
2. Remove three screws and insulators and remove button retainer.
3. Remove contact ring, pivot contact, spring and insulator.
4. Remove lock nut, retaining nut and washer from steering shaft.
5. Remove contact plate.
6. Remove wheel with puller.

1961-62 Deluxe Wheel

1. Twist steering wheel ornament and lift to remove.
2. Remove lock nut, retaining nut and washer from steering shaft.
3. Remove horn ring and contact assembly.
4. Remove contact assembly from horn ring (3 screws).
5. Remove pivot contact, spring and insulator from hub of wheel.
6. Use puller to remove wheel.

1960

1. Twist steering wheel ornament and lift out.
2. Remove two nuts and washer from steering shaft.
3. Remove spacer bushing screws and bushing.
4. Remove horn ring.
5. Remove pivot ring, spring, insulator and contact plate.
6. Remove contact and insulator.
7. Use puller to remove wheel.

1958-59

1. On Standard wheel, remove horn button by pressing down on one side, inserting screwdriver under opposite edge of button and prying upward.
2. On Deluxe wheel, remove wheel ornament by prying up on end. Remove two nuts and washers from plate. Remove plate and insulator, horn ring, upper contact, spring, spring washer, three screws and insulators from lower contact and support. Remove lower contact insulator and support.
2. Remove two nuts from steering shaft and use puller to remove wheel.

1957

1. On Standard wheel, remove horn button by pressing down on one side, inserting screwdriver under opposite edge of button and prying upward.
2. On Deluxe wheel, remove horn ring by removing four screws which retain covers to bottom of horn ring. Remove side plates, horn ring, horn ring adapter bushing screws and related parts.
3. Remove nut from steering shaft.
4. Use puller to remove wheel.

1955-56

1. Remove Deluxe horn ring button by turning counterclockwise.
2. Remove Standard horn button by pressing down on one side, inserting screwdriver under opposite edge of button and prying upward.
3. Remove lock nut, nut, washer, horn ring, insulator and contact assembly.
4. Use puller to remove wheel.
5. When installing, tighten wheel nut to a torque of 25-30 ft. lbs. and tighten lock nut finger tight plus ¼ turn.

STEERING GEAR, REPLACE

1955-57 Standard Gear

1. If car is equipped with power brakes, remove the power unit as outlined previously.
2. Remove horn button and steering wheel.
3. Disconnect turn signal wiring harness at connector under instrument panel and remove turn signal lever.
4. Remove column lower finish plate.
5. Roll back floor mat and remove steering column pedal plates, felts, and felt retainer plate.
6. Disconnect horn and neutral switch wires.
7. Remove gearshift lever.
8. Disconnect gearshift and selector rods from steering column levers.
9. Raise car on hoist, if available, otherwise on high car stands *under both lower control arms* so as to provide clearance for removing steering gear.
10. Remove engine left side apron.
11. Pull pitman arm from gear shaft.
12. Loosen three bolts holding steering gear housing to frame. Then remove two bolts, leaving the front upper bolt to support the steering gear.
13. Remove bolts holding steering column lower bracket to upper bracket on instrument panel.
14. Remove remaining gear-to-frame bolt and remove the steering gear by bringing it down through the floorboard and over steering linkage toward right front wheel. *Be sure to save any shims found between gear housing and frame so they can be reinstalled.* If the car is equipped with NO-ROL the steering gear will have to be removed by way of the driver's compartment, passing the pitman shaft between the pedals.
15. Reverse the foregoing procedure to install the gear.

1958-59

1. Remove steering wheel.
2. Disconnect turn signal wiring harness at connector under instrument panel.
3. Remove turn signal lever.
4. Remove steering column lower finish plate.
5. Roll back floor mat and remove steering felt and felt retainer plate.
6. Disconnect horn wire and neutral safety switch wire.
7. Remove gearshift levers.
8. Disconnect gearshift selector rods from steering column.
9. Remove splash apron.
10. Remove starter motor (1958 only).
11. Remove turn signal wires.
12. Remove pitman shaft arm.
13. Remove bolts holding steering column lower bracket to upper bracket on instrument panel.
14. Unfasten steering gear housing from frame. *Make sure shims found between gear housing and frame are installed in the same position.*
15. *On 1958 models, the gear is removed or replaced from the front of the car with the lower control arm disconnected and the coil spring or air spring removed.*

1960

1. Remove steering wheel.
2. Disconnect turn signal wiring harness at connector under instrument panel.
3. Remove turn signal lever.
4. Remove column lower finish plate.
5. Roll back floor mat and remove steering felt and felt retainer plate.
6. Disconnect horn wire and neutral switch wire.
7. Disconnect gearshift selector rods from steering column.
8. Remove floor pan cover.

9. Remove backup lamp and switch wires.
10. Remove turn signal wires.
11. Remove pitman shaft arm.
12. Unfasten steering gear from frame (3 bolts). Make sure shims found between gear housing and frame are installed in same position when gear is installed.

1961-62

1. Use puller to remove pitman arm from steering gear shaft.
2. Scribe a mark on worm shaft flange and steering shaft and disconnect lower flange from steering shaft.
3. Unfasten gear housing from frame (3 bolts) and remove from car.

POWER STEERING UNIT, REPLACE

1955

1. If equipped with power brakes, remove the power brake unit as outlined below.
2. Hold down the front suspension by compressing the front springs and use a suitable hook with one end in the hole in the cross member and the other end under the lower control arm support.
3. Remove steering wheel.
4. Remove turn signal switch handle and gearshift lever.
5. Remove steering column-to-instrument panel bracket cap.
6. Slide rubber grommet up on steering column jacket.
7. Roll back floor mat and remove pedal plates from floor.
8. Remove back-up light and neutral switch on Hydramatic cars.
9. Disconnect gearshift and selector rods.
10. Disconnect turn signal wires.
11. Disconnect power steering oil lines at gear and secure lines so ends are higher than reservoir to prevent fluid leakage. Install plastic plugs or tape to cover gear and line openings and prevent entry of dirt.
12. Protect all finished surfaces on steering column with masking tape.
13. Raise car on hoist.
14. Remove pitman arm.
15. Remove idler lever support attaching bolts.
16. Remove engine left side apron.
17. Remove brake pedal hairpin spring retainer and slide pedal to right as far as it will go.
18. If car is on a twin post hoist it will be necessary to place stands under both front frame ends and lower the front post approximately 3 feet to allow steering gear assembly to clear hoist.
19. Push steering connecting linkage down and toward rear of car.
20. Unfasten steering gear from frame, removing front upper bolt last.
21. Lower assembly between lower control arm and steering linkage. *Be sure to save any shims found between gear housing and frame so they can be reinstalled.*
22. Reinstall in the reverse order.

1956

1. Remove power brake unit.
2. Remove steering wheel.
3. Remove turn signal switch handle and gearshift lever.
4. Remove steering column-to-instrument panel bracket cap.
5. Slide rubber grommet up column jacket.
6. Remove pedal plates from floor.
7. Remove neutral and back-up light switch wires on Hydra-Matic cars.
8. Disconnect gearshift and selector rods.
9. Disconnect turn signal and horn wires.
10. Disconnect power steering oil lines at gear and secure lines so ends are higher than reservoir to prevent fluid leaking. Install plastic plugs or tape to cover gear and line openings and prevent entry of dirt.
11. Protect all finished surfaces on steering colunm with masking tape.
12. Raise car on hoist.
13. Remove starter motor.
14. Remove pitman arm.
15. Remove left side tie rod end and drop steering linkage.
16. Remove engine left side apron.
17. Remove spring retainer and slide brake pedal to right as far as possible.
18. Push steering connecting linkage down and toward rear of car.
19. Unfasten steering gear from frame, removing front upper bolt last. Then lower steering gear between lower control arm and steering linkage. *Check and keep intact shims that may be present between gear and frame for reassembly.*
20. Reverse the removal procedure to install the steering gear. Then, after filling the reservoir to the proper level with fluid, turn the wheels from stop to stop several times to bleed all air from the system. Replenish the reservoir and install the cap.

1957-58

1. Scribe alignment marks on the steering shaft and worm shaft flanges.
2. Remove two flange attaching nuts and washers.
3. Disconnect pressure and return hoses from valve body.
4. Remove pitman arm.
5. Unfasten gear housing from frame and lift gear out of car.

1959-61

1. Scribe two coupling flanges just above gear and remove flange attaching nuts.
2. Disconnect pressure and return hoses from gear housing.
3. Disconnect pitman arm.
4. Unfasten gear from frame and remove.

MANUAL STEERING GEAR REPAIRS, 1955-62

Disassemble, Figs. 3 and 4

1. Loosen adjusting screw lock nut and remove housing side cover by unscrewing adjusting screw.
2. Loosen lock nut and back off worm bearing adjuster several turns, then remove housing end cover and gasket.
3. Remove adjusting screw from slot in end of pitman shaft making sure shim found on adjusting screw is kept with screw.
4. Remove pitman shaft from housing using care that threads do not damage seal in housing.
5. Loosen worm bearing adjuster lock nut and remove adjuster and lower bearing.
6. Push worm and shaft, with ball nut,

Fig. 3 Manual steering gear. 1955-60 models have a one-piece worm shaft extending up to steering wheel. For 1961-62 a two-piece shaft fastened together by a flange is used

through bottom of housing and remove upper bearing.

7. Remove ball return guide clamps and guides from ball nut, turn ball nut over to remove balls and remove ball nut from steering shaft worm.

Inspection of Parts

1. Clean and inspect all ball and roller bearings and races, including race in housing.
2. Inspect pitman shaft bushings in gear housing and end cover. Replace bushings in housing and replace end cover if bushings are worn excessively.
3. It is advisable to replace pitman shaft grease seal in housing to avoid possible leakage of lubricant. Seal must be installed with feather edge toward inside of housing.
4. Inspect steering shaft for wear or pits in bearing races, which would require replacement of shafts.
5. Check shaft for straightness.
6. Inspect teeth of ball nut and pitman shaft. If scored or excessively worn it is advisable to replace both parts to insure proper mating of teeth.
7. Check serrations of pitman shaft; if twisted, replace shaft.
8. Check fit of pitman shaft adjusting screw and shim in slot in end of pitman shaft. *With shim in place, screw head must be free to turn in slot with zero to .002" end play.* If end play is excessive, selectively fit a new shim, which are furnished in four different thicknesses.
9. Inspect steering column jacket for distortion. A ripple or wavy feeling of jacket surface, particularly at lower end, will usually indicate a sprung jacket. Replace jacket if sprung or otherwise damaged.
10. Inspect control shaft bearing in tube of gear housing, and steering shaft upper bearing in control lever housing support. Replace worn or damaged parts.

Fig. 4 Manual steering gear adjustments

Assemble

To assemble the steering gear, reverse the order of procedure given for disassembly. In addition, observe the following instructions.

1. Lubricate bearings and gears with steering gear lubricant.
2. Use all new gaskets to avoid oil leaks.
3. When assembling ball nut on worm, be sure to place 18 balls in each circuit, making a total of 36 balls.
4. When installing pitman shaft, avoid damaging or turning the feather edge of leather seal in gear housing.
5. Temporarily install steering wheel and adjust worm shaft thrust bearing for proper load and pitman shaft for proper gear lash as described below.

Adjustments

CAUTION:—It is very important when adjusting the steering gear that the adjustments be made in the sequence given below. Failure to do so will result in damage to the steering gear.

1. Disconnect steering connecting rod from pitman arm.
2. Loosen pitman shaft adjusting screw lock nut and back off adjusting screw a few turns, Fig. 4.
3. Remove horn button or ring, etc., to make the steering shaft nut accessible.
4. With an inch pound torque wrench attached to the proper size socket, measure and record at least 30° (1 or 11 o'clock position) off center.
5. When taking torque readings, take a reading pulling the torque wrench to the left and then a reading pulling wrench to the right. Total both readings and take one half of this total as the average torque.
6. Torque required should be between 6 and 10 inch lbs. To correct, loosen worm bearing adjuster lock nut, Fig. 4, and turn adjuster to bring the torque within limits.
7. Retighten lock nut and recheck torque.
8. When worm bearing preload has been adjusted, the pitman shaft adjusting screw should be turned clockwise until a pull equal to the worm bearing preload *plus 2 to 6 inch lbs.* is required to turn the wheel through center.
9. Tighten lock nut and recheck adjustment.
10. Connect steering connecting rod to pitman arm. Set steering wheel spokes in straight ahead position (mark on steering shaft up). If road wheels are not straight ahead, adjust steering tie rods.

Speedometer, Radio and Windshield Wiper

SPEEDOMETER REPLACE

1955-56

Disconnect speedometer cable and remove lamp sockets from back of speedometer. Remove lamp socket wire harness from clip on left hand side of speedometer. Remove three screws from face of speedometer. Remove speedometer by tipping top out of panel, then lifting out. Now remove three screws which fasten speedometer to assembly.

1957

1. Remove gauge cluster simply by disconnecting wires and remove three attaching nuts from the back.
2. Remove radio knobs and radio trim plate attaching nuts.
3. Remove instrument panel trim plate (6 screws).
4. Disconnect speedometer cable, wiring and oil pressure gauge line.
5. From face of instrument panel, remove two screws which retain speedometer to instrument panel.
6. Pull speedometer out of panel.
7. Detach lamp sockets from speedometer and remove unit.

1958

1. Disconnect speedometer cable and wiring.
2. Remove three nuts from back of speedometer case.
3. Pull speedometer out of panel through rear.

1959 Safeguard Speedometer

1. Disconnect electric wire located at rear top of speedometer case.
2. Remove lamp sockets and speedometer cable from speedometer unit.
3. Remove instrument cluster from panel.
4. Remove two nuts and clamps holding speedometer in cluster housing.
5. Lift speedometer and case from cluster housing.

1959 Standard Speedometer

1. Remove instrument cluster from below.
2. Remove two nuts and retainers and lift speedometer from cluster.

1960

1. Remove 8 screws.
2. Remove clock or dummy plate (remove safeguard knob if equipped).
3. Remove back of cluster housing (remove clip on safeguard point and remove wire).
4. Remove speedometer (2 screws).
5. Reverse above procedure to install.

1961-62

1. Disconnect Safeguard control cable on cars so equipped (pull straight out).
2. Remove speedometer cluster.

3. Remove cluster face plate and lens by unsnapping face plate from housing.
4. Remove three screws on back of cluster at cable area.
5. Remove speedometer and instruments. If equipped with Safeguard speedometer, disconnect ground wire at clip terminal and also wire retainer clip. Carefully note routing of wires before removing ground wire.
6. Remove two screws retaining numeral plate and remove speedometer.

RADIO REPLACE

1955-56

Tuner—

1. Disconnect power lead and dial light lead from fuse block and remove wires from clips.
2. Remove connecting cable from audio power unit.
3. Remove antenna lead at connector between tuner unit and audio power unit.
4. Remove nuts from stud at right rear side of tuner unit.
5. Remove control knobs, nuts and finish plate.
6. Remove screw on either side of tuner and remove tuner by pulling outward.

Audio Power Unit—

1. After removal of tuner unit, remove antenna lead.
2. Remove screw at top left side of audio power unit.
3. Support unit and remove retaining screws from bottom of instrument panel and remove unit.

1957

De Luxe Radio—It is first necessary to remove the glove box. Then take off control knobs and nuts from shafts. Remove nut from brace fastened to left side of radio and lift out.

Electramatic Model—It is first necessary to remove the glove box. The tuner is retained by nuts behind the control knobs and by a brace attached to the left side. The audio power unit is retained at the front by two screws through the flange of the instrument panel and at the rear by a bracket attached to the underside of the cowl.

1958

1. Remove control knobs and wing knobs by lining up hole in bottom of chrome escutcheon and hole in winged knob and loosen. Allen set screw.
2. Remove two hex nuts.
3. Remove screw from bracket retaining radio to instrument panel. *If car is Air Conditioned, it will be necessary to remove the center air outlet before the radio bracket screw can be removed.*
4. Remove radio from panel and disconnect radio-to-fuse block wire antenna and speaker leads.

1959-60 Non-Portable Type

1. Remove glove compartment.
2. Remove control knobs.
3. Remove large hex nuts.
4. Remove screw from radio support bracket at rear of receiver.
5. Remove radio through glove compartment opening.

1961-62

1. Remove glove compartment, control knobs and large hex nuts.
2. Remove nut and washer from radio support bracket on left side of radio.
3. Remove radio-to-fuse block wire, antenna lead in wire and speaker leads.
4. Remove radio through glove compartment door.

WINDSHIELD WIPER

1955-58

The removal and servicing of the windshield wiper motor and transmission mechanism are fairly obvious operations. The only differences in the complete wiper assembly between vacuum and electrically-operated, are in the wiper motor, wiper arms and blades. The transmission, cable drives and cable tensioners are exactly the same on either installation.

1959-62

1. To remove wiper motor, remove arms and blades.
2. Remove both retaining nuts, cam parts, washers and escutcheons.
3. Remove ventilator grille.
4. Remove link retainer.
5. Disconnect all electrical connections and washer hoses.
6. Unfasten and remove motor and gear box assembly (4 screws).

PONTIAC TEMPEST

Specifications for the optional V8 engine are tabulated on the pages immediately following this index. For service procedure see the Buick Special Chapter

SERIAL & ENGINE NUMBER LOCATION

On Machined Pad On Front Right Side Of Block

Tempest 1961

1962

Engine Section

See Buick Special Chapter for Service Procedures on V8 Engine

ENGINE, REPLACE

1. Remove hood, radiator and heater hoses at engine.
2. Disconnect wiring harness at engine units, engine ground straps, fuel line at fuel pump, vacuum modulator line at transmission hose connection, accelerator rod at engine lever and exhaust pipe at manifold.
3. Remove front fender cross brace and fan and pulley.
4. Raise front of car and place wood block at rear of engine to prevent damage to distributor if engine rocks to rear.
5. Disconnect propeller shaft and torque tube from rear of engine and remove engine support at cross-member.
6. Raise engine and move forward to clear firewall and heater.
7. Reverse removal procedure to install the engine. *However, be sure to follow instructions for installing the propeller shaft as outlined in the Propeller Shaft Section. Failure to follow procedure may result in damage to drive line.*

CYLINDER HEAD

1. Remove intake manifold.
2. Disconnect breather pipe or hose from vent valve and remove push rod cover.
3. Remove bolts attaching exhaust manifold to head.
4. Remove rocker arm cover.
5. Loosen rocker arm nuts and rotate rocker arms so push rods can be removed.
6. Lift out push rods and tag them so they can be reinstalled in original locations.
7. Remove head bolts and lift off head.
8. Note that there are three different length bolts used. When installed properly, they will project an equal amount from their bosses. Do not use sealer on bolt threads. When installed, tighten rocker arm nuts to 15-25 ft. lbs. torque.

Cross section of four cylinder engine

ROCKER ARM STUDS

Rocker arm studs are replaceable providing a press of at least two tons capacity is available. Both standard and .003″ oversize studs are available. If replacing a loose stud, measure stud diameter with a micrometer. Standard size studs should measure .4340″ to .4345″. If stud is loose because it is undersize, replace with standard stud. If loose because hole is oversize, replace with .003″ oversize stud. No reaming operation is necessary.

1. Remove cylinder head.
2. With rocker arm removed, file two slots $\frac{3}{32}$″ to ⅛″ deep on opposite sides of stud, Fig. 1. Top of slots should be ¼″ to ⅜″ below thread travel.
3. Place special washer (J-8934-3) at bottom of stud, Fig. 2. Position stud remover (J-8934-1) on stud and tighten screws securely with $\frac{5}{32}$″ Allen wrench. Place spacer (J-8934-2) over stud remover.
4. Thread ⅞″ standard nut on stud remover and turn nut until stud is out of cylinder head.
5. Remove plugs, Fig. 3, from ends of cylinder head oil gallery and clean out metal deposits and foreign matter.
6. Position rocker arm on new stud and place installer (J-8927) on stud in place of rocker arm ball.
7. Coat stud with white lead and oil and, with cylinder head mounted on press so studs are vertical, position new stud with rocker arm stud installer over hole in head, Fig. 4.
8. Press stud in head until it is in about halfway ($\frac{7}{16}$″).
9. Position valve train gauge (J-8928) in push rod hole so that it seats properly in rocker arm.
10. With valve seated, slowly press stud into head until gauge projects about midway between end of gauge and

Fig. 1 Slots filed in rocker arm stud

Fig. 2 Tools positioned to remove rocker arm stud

Fig. 3 Location of cylinder head oil gallery plugs

Fig. 4 Positioning rocker arm stud for installation

the step with respect to the gasket surface of the head, Fig. 5.

11. Remove stud installer, rocker arm and ball. Blow air through hole in new stud to insure that passage is not restricted. Blow air through oil gallery to remove any foreign matter. Replace plugs in ends of oil gallery.
12. Check oil passages from oil gallery to all studs. Install rocker arm and ball and install nut loosely.
13. Install cylinder head and tighten to specified torque. Tighten rocker arm nuts to a torque of 15-25 ft lbs.

VALVE ARRANGEMENT

Front to Rear . . . . . E-I-I-E-E-I-I-E

VALVES, GRIND

After removing valves and springs from cylinder head, scrape all carbon from combustion chambers and valves. If wire brushes are used for cleaning carbon, use care to avoid scratching valve seats and valve faces. Clean all carbon and gum deposits from valve guides.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding the valve must be replaced. In other words the valve head margin must be at least $\frac{3}{64}$", otherwise the valve must be replaced. This margin is the area above the contact surface of the valve face.

Inspect the valve seats in the head for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul it is advisable to reface the valve seats regardless of their condition.

Reface valves and true up seats to the angles listed in the *Valve Specifications* chart. Cutting a valve seat results in lowering the valve spring pressure and increases the width of the seat. The nominal width of a valve seat is $\frac{1}{16}$". If valve seat is over $\frac{5}{64}$" after truing up, it should be narrowed to specified width by using a flat stone.

Improper hydraulic valve lifter operation may result if valve and seat have been refinished enough to allow the end of the valve stem to raise approximately .050" above normal position. In this case it will be necessary to grind off the end of the valve stem or replace parts.

Fig. 5 Checking stud height

Fig. 6 Valve nomenclature. Tempest engine has an inner and outer spring for each valve

Test valves for concentricity with seats and for tight seating. Valves can be tested by lightly coating the valve face with Prussian blue and turning the valve against its seat. This indicates whether the seat is concentric with the valve guide *but does not prove that the valve face is concentric with the valve stem, or that the valve is seating all around.* After making this test, wash all blue from the surfaces, lightly coat the *valve seat* with blue and repeat the test to see whether a full mark is obtained on the valve. *Both tests are necessary to prove that a proper seat is being obtained.*

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 6. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary.

Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16″, and since the acceptable valve head margin is approximately $\frac{3}{64}$″ to $\frac{5}{64}$″, one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the vales, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

Wash all valve springs with a suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications in the *Valve Specifications* table within 10 per cent should be replaced. Likewise any spring that stands shorter than the new spring used for comparison should be discarded.

VALVE GUIDES

Valve guides are cast integral with the cylinder head. Valves with oversize stems are available in .001″, .003″ and .005″ larger than standard.

Oversize reamers are required to enlarge valve guide holes to fit the oversize stems. For best results when installing .005″ oversize valve stem use a .003″ oversize reamer first and then ream to .005″ oversize. Always reface the valve and valve seat after reaming valve guide. Valves are marked .001, .003 or .005 with colored ink.

Fig. 7 Hydraulic valve lifter parts. Some lifters have a ball check valve spring which fits under the ball inside the check valve retainer.

Fig. 8 Front of engine with cover removed

HYDRAULIC VALVE LIFTERS

Failure of an hydraulic valve lifter, Fig. 7, is generally caused by an inadequate oil supply or dirt. An air leak at the intake side of the oil pump or too much oil in the engine will cause air bubbles in the oil supply to the lifters, causing them to collapse. This is a probable cause of trouble if several lifters fail to function, but air in the oil is an unlikely cause of failure of a single unit.

The valve lifters may be lifted out of their bores after removing the rocker arms and push rods. Adjustable pliers with taped jaws may be used to remove lifters that are stuck due to varnish, carbon, etc.

To disassemble, press down on the center of the push rod cup. Using a pointed tool, remove lock wire from the groove while holding cup down. Invert lifter and slide out push rod cup, plunger, ball, retainer and spring.

To assemble, place the ball on its seat in the lower end of the plunger while holding the plunger upside down. Position the ball retainer and spring over ball and end of plunger. Lower the body over the plunger. Turn the assembly right side up and fill the plunger with clean engine oil. Jiggle the ball with a small piece of wire until oil drains out of plunger into the body and trapped air is released from the body. Refill the plunger with oil, place the push rod cup on the plunger and position the lock wire over the cup, locking it in its groove.

TIMING COVER

1. To remove cover, drain radiator.
2. Remove generator, fuel pump and vibration damper.
3. Remove water hose at cover.
4. Remove cover attaching bolts.
5. Loosen cover-to-intake manifold draw bolt and remove cover.
6. Reverse foregoing procedure to install cover and torque oil pan-to-cover screws to 15 ft. lbs.

TIMING CHAIN

1. To remove, take off cover, fuel pump eccentric and crankshaft oil seal.
2. Remove chain tensioner spring and bumper, Fig. 8. *Right hand bumper must be removed before spring is removed because of hook in end of spring. Do not attempt to remove spring by stretching or twisting as spring may be damaged.*
3. Align timing marks on sprockets to simplify proper positioning on reassembly, Fig. 9.
4. Slide chain and sprockets off shafts.
5. Install new chain and/or sprockets, making sure marks on sprockets are aligned exactly on a straight line passing through shaft centers. Camshaft should extend through sprocket so that hole in fuel pump eccentric will locate on shaft.
6. If tensioner bumpers are worn excessively, replace them. Install chain tensioner assembly, crankshaft oil seal, fuel pump eccentric, bushing and cover.

CAMSHAFT

1. To remove, take off grille lower panel, grille and hood latch as an assembly.
2. Remove front bumper, radiator, intake manifold, timing cover, distributor, chain and sprockets, valve lifters and camshaft thrust plate.
3. Pull out camshaft using care not to damage bearings.
4. Reverse removal procedure to install, being sure to install camshaft

Fig. 9 Valve timing marks

Fig. 10 Checking bearing clearance with Plastigage

thrust plate, indexing slot in plate with slot in block.

CAMSHAFT BEARINGS

Camshaft bearings can be replaced while the engine is disassembled for overhaul or without completely disassembling the engine after removing the camshaft.

Special removing and installing equipment is required to replace the bearings. The notch in the edge of the bearing is used to properly position the bearing, with respect to the oil holes, when installed. When bearings are installed at the factory, the notches all face the front except the one in the rear bearing. In the field it is necessary to install bearings with the notch facing the rear.

Coat inner diameters of all bearings with oil and install camshaft. Rotate camshaft through several revolutions to make sure it is completely free. If any tight spots are found, remove camshaft and carefully polish down the center journal slightly. If still not free, polish the front and rear journals slightly. If any particular bearing causes binding in the camshaft, replace that bearing also.

PISTONS & RODS, REMOVE

After removing the cylinder head, examine the cylinder bores above the ring travel area. If bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of piston during removal.

Remove connecting rod caps and push pistons and rods out of cylinders, using care to prevent rod bolts from contacting and nicking crankshaft journals.

Make sure the rods and pistons are properly numbered so that they can be reinstalled in original locations. It is advisable to install caps on rods to avoid mixing parts.

PISTON & ROD, ASSEMBLE

All pistons have an "F" cast on the front side. There is also a notch cast in top of the high compression piston head and two notches cast in the standard compression piston head at the front to facilitate proper installation.

One side of the connecting rod has large machined bosses. This side of the rod should be installed toward the front of the engine. In other words, the large boss on the rod and the "F" side of the piston should be installed toward the front of the engine.

PISTONS

If the pistons are to be reused with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an old piston ring, filing the broken end to a sharp, square edge and using it to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material.

Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Rinse the piston in solvent and wipe off the carbon on the sides of the piston. *Never use a wire brush to clean a piston* as the brush will round off the edges of the ring lands. Pistons showing scuffed or scored skirts should be scrapped. Examine the ring lands carefully for cracks. If the piston is in the least bit doubtful, it should be discarded.

PISTON RINGS

When new piston rings are installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and

Fig. 11 Tool for removing upper main bearing shells

Fig. 12 Installing rear main bearing oil seal

a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gaps of rings, place the ring in the cylinder in which it will be used. Square it in the body by tapping with the lower end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of rings carefully with a smooth file.

PISTON PINS

Piston pins are a pressed fit in the upper end of the connecting rod and a slide fit in the piston bosses.

ROD BEARINGS

Connecting rod bearings are of the precision insert type and if worn can be replaced without removing the rod assembly by removing the cap and replacing the upper and lower halves. The clearance between the rod bearing and the crankshaft can be measured by the use of Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft journal and bearing insert.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the cap.
3. Reinstall cap and tighten the bolts to the torque listed on the *Engine Tightening Data* table.
4. Remove bearing cap and determine bearing clearance by comparing the width of the flattened Plastigage at its widest point with the graduation on the Plastigage envelope. The

Fig. 13 Exploded view of oil pump

number within the graduation on the envelope indicates the clearance in thousandths of an inch, Fig. 10.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearing with .005″ to .015″ cardboard (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out, Fig. 11.
3. Place a new upper shell on the crankshft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Tightening Data* table.

CRANKSHAFT OIL SEAL

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool, Fig. 12. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜″ from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the sme time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

OIL PAN

1. To remove, drain oil and remove exhaust crossover pipe.
2. Support engine and remove front crossmember.
3. Remove flywheel housing front shield and lower cover.
4. Unfasten and remove oil pan.

OIL PUMP

To remove pump, take off oil pan. Remove pump attaching screws and carefully lower pump away from block with one hand while removing pump drive shaft with the other hand.

When disassembling the pump, mark gears before removing them so they have the same relationship when they are reinstalled, Fig. 13. Clean and inspect all parts, discarding any that are worn or otherwise damaged.

To assemble, install drive and driven gear as marked before disassembly. Install cover and turn drive shaft by hand to insure that it turns freely and has a slight amount of end play. Torque cover bolts to 10-20 ft. lbs. Install pressure regulator ball, spring and retainer, tightening retainer to 8-18 ft. lbs. *Do not attempt to change oil pressure by varying the length of the pressure regulator valve spring.* Install pump to engine and torque bolts to 20-35 ft. lbs.

RADIATOR

To remove radiator, drain system and disconnect hoses. Remove radiator fan shield and radiator.

WATER PUMP

To remove water pump, which is *serviced only as an assembly,* drain cooling system. Remove fan belt, fan and pulley. Unfasten and remove pump from engine.

When pump is installed on engine, drain hole will be at bottom. Tighten pump attaching nuts to 15 ft. lbs.

DISTRIBUTOR, REPLACE

1. To remove, disconnect distributor-to-coil primary wire.
2. Remove distributor cap and crank engine so rotor is in position to fire No. 1 cylinder and timing mark on vibration damper is indexed with pointer.
3. Remove vacuum line, distributor clamp screw and hold-down clamp.
4. When removing distributor, note that the rotor will rotate as the distributor is pulled out of the block. Note the relationship of the rotor and housing after removal so that the rotor can be set in the same position when the distributor is being installed. Always set distributor in an upright position so oil from distributor shaft will not run out onto breaker plate and points.
5. Reverse removal procedure to install distributor, being sure that No. 1 piston is up on its compression stroke and that the rotor is in the position to fire No. 1 spark plug. Then check and adjust ignition timing.

IGNITION TIMING

With distributor vacuum line disconnected and car operating at normal idle speed or below, set ignition timing. See *Tune Up Chart.*

STARTER, REPLACE

To remove starter, disconnect cable from battery and cable and solenoid wire from starter solenoid. Unfasten and remove starter from engine.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck in either the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Then move the valve up and down a few times to work the oil in. *Do not use engine oil to lubricate the valve as it will leave a residue which hampers valve operation.*

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

Engine Stalls, 1961

If stalling occurs during warm-up on cars with automatic transmission, change choke setting from "Index" mark to two notches rich on 7019062 and 7019066; one notch rich on 7019079.

ROCHESTER CARBURETOR ADJUSTMENTS

★See Tune Up Chart for hot idle speed.

ROCHESTER NOTES

Choke Rod. Adjust

With idle speed screw on second step and against high step of cam, bend choke rod as necessary to obtain the proper clearance between lower edge of choke valve and inner wall of air horn. Clearance is .081" on BC, .052" on 2GC and .055" on 4GC.

Idle Vent, Adjust

4GC UNITS—Open primary throttle valve to a point where idle vent valve just closes. With a 55/64" gauge, measure between top of air horn casting and bottom of pump plunger rod. To adjust, bend tang on pump lever.

Fig. ①—B and BC float level.

Fig. ②—B and BC float drop.

Fig. ③—With throttle valve wide open, bend tang on throttle lever to obtain specified clearance between choke valve and inner wall of air horn.

④—With fast idle on 4GC and hot idle on BC properly adjusted, shut off engine. Rotate fast idle cam so that fast idle screw rests on second step of fast idle cam with screw resting against top step. Clearance between contact screw and contact on throttle lever should be as specified. To adjust, turn contact screw as required.

Fig. ⑤—2GC float level.

Fig. ⑥—2GC float drop.

Fig. ⑦—With pump rod in outer hole of lever, back out idle screw until throttle valves are fully closed. Measure distance between top of air horn to top of pump rod. If dimension is not as specified, bend pump rod as required.

Fig. ⑧—With throttle valves wide open, clearance between upper edge of choke valve and inner wall of air horn should be as specified. To adjust, bend tang on throttle lever.

Fig. ⑨—With throttle valves closed, measure from top of air horn casting to bottom of pump plunger rod. To adjust, bend pump rod as required.

Fig. ⑩—4GC float level.

Fig. ⑪—4GC float drop.

Fig. ⑫—With throttle valves fully open, bend tang on fast idle cam to obtain the dimension specified between top of choke valve and inner wall of air horn.

⑬—With fast idle screw resting on top step of cam, adjust fast idle screw to obtain the engine rpm specified.

ROCHESTER NOTES

continued

Fig. ⑭—After making pump adjustment, adjust idle vent valve as shown.

⑮—With engine at hot idle and transmission in neutral, disconnect vacuum hose from dashpot and plug open end of hose. Adjust dashpot contact screw to obtain the engine speed listed. Hold sleeve next to diaphragm from turning while tightening screw.

Fig. ⑯—4GC float level

⑰—See "Engine Stalls" service note.

Clutch & Standard Transmission Section

CLUTCH PEDAL, ADJUST

1. Back off silencer bumper so it does not touch pedal.
2. Adjust position of stop bracket to establish correct pedal height, Fig. 1.
3. Adjust silencer bumper so that it just contacts clutch pedal on pedal return.
4. Loosen lock nut on clutch rod.
5. Remove spring, washer and cotter pin from rear end of clutch fork rod.
6. Pull end of clutch fork toward rear of car until release bearing is in solid contact with fingers on pressure plate. This is the zero lash position.
7. With fork held back as described above, run adjusting nut back against fork. Then adjust lash by turning 3½ turns for a used driven plate or 4½ turns for a new driven plate. Tighten lock nut.
8. As a final check, observe clearance between release bearing and fingers with clutch released. This should be a minimum of .060". Check clutch pedal feel and return action.
9. Install flywheel housing lower cover.

Fig. 1 Clutch pedal clearance

CLUTCH, REPLACE

1. To remove clutch, disconnect stabilizer bar at body frame rail.
2. Disconnect exhaust pipe.
3. Disconnect front of torque tube from clutch housing. Support torque tube at front after dropping front of tube enough to permit access to clutch.
4. Disconnect clutch rod from fork.
5. Disconnect clutch link from clutch housing stud.
6. Remove clutch housing with components intact.
7. Mark relationship between clutch cover and flywheel to maintain original balance if same clutch is being installed.
8. Remove clutch assembly.
9. Install clutch by reversing removal procedure. Torque clutch cover bolts 25-35 ft. lbs.

GEARSHIFT CONTROL

Removal

1. Loosen clamp nut securing control rod to coupling.
2. Remove bolts securing gearshift lever and housing to torque tube.
3. Move gearshift lever and housing toward front of car, removing control rod from coupling.
4. Remove cotter and clevis pins securing coupling to manual shift shaft, Fig. 2.
5. Remove coupling and boot from shaft.

Fig. 2 Gearshift control rod coupling

Fig. 5 Manual shift transmission

Installation

1. Position manual shift shaft in 1st gear position. To locate 1st gear position in transmission, place shift shaft in neutral, turn counterclockwise, and pull shaft to forward position.
2. Install shift shaft and coupling boot, Fig. 2. Install coupling on shaft and secure with clevis and cotter pins. Slot in coupling must be in up position.
3. Slide control rod on coupling with finger in coupling slot, Fig. 3. Secure shift lever and housing to torque tube and tighten bolts to 10-15 ft. lbs.
4. Install pin in control rod alignment hole, Fig. 4, and push control rod forward into shift lever and housing until pin hits housing flange.
5. Secure control rod to coupling by tightening clamp nut to 10-20 ft. lbs.
6. Remove pin from alignment hole and install boot over housing shoulder.

Fig. 3 Gearshift control rod coupling finger

TRANSMISSION REPAIRS

To remove and replace the transmission, refer to Rear Axle, Propeller Shaft and Torque Tube Section.

Disassemble

1. Remove extension housing, Fig. 5.
2. Remove top cover and gasket.
3. Remove snap ring from mainshaft groove at rear of case.
4. Drive out clutch gear and bearing by driving on mainshaft.
5. Continue to drive or press mainshaft out of case and remove thrust washer. *Be sure synchronizer ring tangs are aligned with mainshaft splines prior to driving out shaft, otherwise damage to ring and shaft splines will occur.*
6. Strip mainshaft parts by lifting them out through top cover opening.
7. Expand retaining ring and start mainshaft bearing out by tapping on outer race; then drive bearing out of case.
8. Remove detent cover plug and remove 2nd-3rd gear detent spring and ball.
9. With suitable punch, drive out roll pin securing 2nd-3rd shift fork to shaft, Fig. 6, then tap shaft toward front with a drift and remove fork, shaft and roll pin.

Fig. 4 Gearshift control rod alignment pin

Fig. 6 Transmission shift forks

Fig. 7 Transmission shift finger

Fig. 8 Countergear needle bearings installed

Fig. 9 Clutch gear needle bearings installed

Fig. 10 Removing or installing synchronizer ring

Fig. 11 Position of energizing spring

Fig. 12 Reverse idler gear lock pin

Fig. 13 Mainshaft components assembled

10. Remove interlock from detent cavity. Then remove 1st-reverse shift fork and shaft in same manner as 2nd-3rd fork.
11. Remove shift finger, Fig. 7.
12. Remove manual shift shaft seal from rear lower left corner of case.
13. Drive countershaft out from front of case, using a dummy shaft (or tool J-5777) to hold needle bearings in place.
14. If necessary, drive reverse idler shaft lock pin into shaft, then drive shaft out of case through hole at rear of case. Remove caged needle bearing and thrust washer used at rear of reverse idler gear.
15. Remove mainshaft bearing retainer ing from case.

Assemble

Refer to Figs. 8 to 13 for assembly details of several components and use Fig. 5 as a guide when assembling the transmission.

1. Install manual shaft seal.
2. Install assembled countergear, Fig. 8.
3. Install reverse idler gear, Fig. 12.
4. Insert manual shift shaft through seal in case. Position actuating finger and secure to shaft (see Fig. 7) with two lock tabs and capscrews, tightening to 5-7 ft. lbs. Bend lock tabs over screw heads. Install detent ball and spring (in that order) through hole in side of case. Tap ball and spring to be sure spring is resting on bottom of cavity.
5. Start roll pin into 1st-reverse fork. Insert fork shaft through lower hole at front of case with three detents facing detent ball and slip fork on shaft. Depressing ball, press shaft over ball to the center detent position. Secure fork to shaft with roll pin. Coat interlock with oil and install in detent cavity. *Be sure* shift finger is engaged with 1st-reverse shift fork prior to installing 2nd-3rd shift fork, Fig. 6.
6. Start roll pin into fork. Insert 2nd-

Fig. 14 Four speed manual transmission disassembled

3rd fork shaft through front of case with three detents facing away from interlock and slip fork onto shaft. Secure with roll pin.

7. Insert detent ball and spring (in that order) for 2nd-3rd shift fork and install detent cavity cover and gasket. Torque cover bolts to 25-35 ft. lbs. After installing detent plug, check for free movement of manual shift shaft in all gear positions.
8. Place assembled clutch sleeve, 1st-reverse sliding gear and 2nd gear in case, Fig. 13. Make sure 1st-reverse gear and shoulder on clutch sleeve are in proper forks.
9. Place mainshaft in clutch gear and, from front of case, insert mainshaft through clutch sleeve and 2nd speed gear. *Be sure tangs of synchronizer ring are aligned with mainshaft splines before installing mainshaft and that clutch gear slots, Fig. 9, are properly aligned with larger tangs on synchronizer ring.*
10. Drive clutch gear bearing into place.
11. Install thrust washer on mainshaft with its oil grooves toward 2nd gear. Install mainshaft bearing retainer ring. Install mainshaft bearing with ring groove toward case and, with retainer ring expanded, drive bearing onto mainshaft.
12. Install a ½" deep socket in clutch gear and continue to drive on mainshaft bearing until snap ring groove is accessible. Install snap ring.
13. Check end play of mainshaft by inserting feeler gauge between snap ring and bearing inner race. Final end clearance must be .004" maximum. Use a snap ring of a size that will establish this clearance. Snap rings are available in four thicknesses ranging from .086" to .097". After making this check, drive mainshaft forward into case until snap ring contacts inner bearing race.
14. Check for free movement of shift shaft to be sure each gear position may be easily obtained. Install top cover, filler plug and extension housing.

4 SPEED TRANS.

1. To disassemble the transmission, refer to Fig. 14, and remove the side cover.
2. Remove plug, detent spring and ball from 3-4 detent channel, Fig. 15.
3. Drive roll pin from 3-4 shift fork. Remove 3-4 shift shaft and fork. Shaft can be driven from case in either direction.
4. Remove plug, spring and detent ball from 1-2 detent channel, Fig. 16.
5. Move 1-2 shift fork into second gear. Then remove roll pin securing fork to shaft. Remove fork and shaft by tapping shaft out of case in either direction. Do not lose interlock pin from shaft or case.
6. Remove two snap rings at clutch gear.
7. Remove clutch gear bearing with a suitable puller.
8. Remove two snap rings securing rear mainshaft bearing retainer, Fig. 17.
9. Remove mainshaft with assembled gears and rear bearing retainer (with sliding sleeve full forward). It may be necessary to jiggle the output shaft, making sure clutch gear does not separate from mainshaft.
10. Drive roll pin from reverse shifter head, then remove shifter head and shaft from case by tapping shaft out in either direction.
11. Drive out reverse idler gear and reverse shifter fork shafts from case by driving rearward. Use care not to lose key used in reverse idler gear shaft. Remove idler gear and reverse shifter fork from case, Fig. 18.
12. Remove reverse shifter lever by lifting off its pin in case.
13. To remove countergear, drive countershaft rearward until it is fully disengaged from case, using a dummy shaft to hold bearings, etc., in place inside countergear.
14. Remove one thrust washer and remove countergear from case, using care not to tip countergear to prevent needle bearings from falling out.
15. Remove two countergear thrust washers from case.
16. Using a magnet or by tipping the case, remove two interlocks and detent ball and spring remaining in 3-4 detent channel.
17. Remove shift finger from selector shaft (2 screws). Then remove shifter shaft plug in rear of case. Tap shaft rearward from case through hole.
18. With suitable tool, remove reverse inhibitor plug, spring, ball seat and ball from top of case, Fig. 19. Remove other plug, spring and reverse inhibitor plunger, Fig. 20.

Disassemble Mainshaft

1. Place clutch gear downward against bench top and carefully lift mainshaft out of clutch gear to prevent disturbing clutch gear roller bearings. *Be sure to keep needle retainer washer with clutch gear.*
2. Remove special snap ring from front of mainshaft, then slide or press 3-4 synchronizer unit with blocker rings, third speed gear, radial needle bearing, and second speed gear from

Fig. 15 Detent ball, spring and plug from 3-4 detent channel

Fig. 16 Detent ball, spring and plug from 1-2 detent channel

Fig. 20 Reverse inhibitor

Fig. 21 Synchronizer spring and hub installed

Fig. 22 Blocker rings

Fig. 24 Shift fork shafts

Fig. 23 Assembled mainshaft

Fig. 25 Fork shaft partially installed

mainshaft. Remove 1-2 synchronizer from hub and *do not lose keys.*

3. Remove rear bearing selective snap ring, then remove rear bearing retainer and first speed gear as an assembly. *Be careful not to lose first speed gear thrust washer.*
4. Remove 1-2 blocker rings.
5. Press mainshaft out of 1-2 synchronizer unit and first speed gear sleeve.

Assemble Transmission

Reverse the order of disassembly to assemble the transmission, referring to Fig. 1 and Figs. 21 through 25. Observe the following:

1. When installing rear bearing retainer and bearing on rear of mainshaft, the end play between rear face of rear bearing and snap ring should be a maximum of .005″. The thicknesses of snap rings are available to obtain this result.
2. When installing assembled mainshaft into the case, shift the synchronizers into second and fourth simultaneously (both full forward) to provide clearance to pass countergear. Insert mainshaft through rear bearing bore. Align rear bearing retainer snap ring cut outs with snap ring cut outs in rear of case, then tap rear bearing retainer into case until flush with rear face. *Make sure clutch gear stays securely in place.*
3. Retain clutch gear in bearing with selective snap ring. With proper snap ring installed, maximum end play between bearing and snap ring will be .005″.
4. Prior to installing side cover, test operation of shift forks by actuating shift selector lever with a small pin punch inserted in hole in shifter shaft.

Automatic Transmission Section

Fig. 1 Automatic transmission and differential carrier (transaxle)

DESCRIPTION

This transmission, Fig. 1, consists of an air cooled, three element torque converter and a two speed planetary transmission. The transmission is attached to the differential carrier to form a transmission-axle (transaxle) assembly. As a result the converter is mounted on the opposite side of the carrier from the transmission. Two shafts run axially (one inside the other) through the differential pinion shaft, transmitting torque from the engine to the converter and back to the transmission. Fig. 2 shows a schematic drawing of the transaxle components.

Fig. 2 Schematic drawing of transaxle

Fig. 3 Shift linkage check diagram

MAINTENANCE

Adding Oil

Oil should be added only when the level is near the "ADD" mark on the dipstick with oil at normal operating temperature. The difference in oil level between "FULL" and "ADD" is one pint.

In order to check the oil level accurately, the engine should be idled with the transmission oil at normal operating temperature and the selector lever in neutral (N) position.

It is important that the oil level be maintained no higher than the "FULL" mark. Do not overfill. If oil is added which brings the level above the full mark, the planetary unit will run in the oil, foaming and aerating the oil. This will cause malfunction of the transmission due to improper application of the band or clutches and excessive temperature.

Changing Oil

No periodic draining of the transmission oil is recommended. When transmission requires repair, drain the oil by loosening the filler tube attaching nut in the oil pan and allow oil to drain (no drain plug is provided).

To refill the transmission, tighten the filler tube nut and add 2 quarts of approved automatic transmission oil, using filler tube and funnel. Start engine and allow it to idle in neutral 3 to 5 minutes to warm the oil. Then check the level and add as required to raise the level to the "FULL" mark. Assuming that the converter is not drained (since it is welded) and allowing for nominal spillage or draindown, approximately 3 quarts of oil will be required for refill.

Fig. 4 Gauging manual valve

EXTERNAL LEAK CHECK

If the transmission is found to be consistently low on oil, a thorough inspection should be made to find and correct all external oil leaks.

All mating surfaces, such as the front pump, oil pan rail, filler tube, governor, and the attachment to the differential carrier should be carefully examined for signs of leakage.

The vacuum modulator must also be checked to insure that the diaphragm has not ruptured as this would allow transmission oil to be drawn into the intake manifold of the engine. Usually, the exhaust will be excessively smoky if the diaphragm ruptures. Check level in the differential to be certain oil is not leaking from the transmission to the differential carrier.

Fig. 5 Throttle valve pressure adjusting nut and manual valve lever lock screw

ADJUSTMENTS

Neutral Switch

The starter neutral switch is located on the rear of the gearshift control and indicator assembly. Properly adjusted, the switch should prevent engine cranking in any position other than "N". If engine cranks in any other position, adjust by loosening the two switch mounting screws and moving switch as required.

Shift Linkage Check

1. Start engine. If cold, allow 2 to 3 minutes for transmission oil to warm up.
2. With engine at normal idle speed, move selector lever up from "N" toward "R" and note by feel the point at which reverse clutch applies. Properly adjusted, reverse clutch should apply within band from tooth peak to full Reverse detent, Fig. 3.
3. Make same check while moving selector lever from "N" to "D". Properly adjusted, the low band should apply as selector lever indicator is felt to be between tooth peak separating Neutral from Drive and full Drive Detent.
4. Unless shifts are obtained at points illustrated in Fig. 3, the shift linkage should be adjusted as follows:

Shift Linkage, Adjust

1. Drain oil from transmission and remove oil pan.
2. Place selector lever in driving compartment in "D".
3. Insert gauge (J-8365), Fig. 4, into

Fig. 6 Four cylinder throttle linkage. Early 1961

Fig. 7 Four cylinder throttle linkage. Late 1961

manual valve bore with tab of gauge upward so it engages forward part of valve body.

4. With gauge in place, push forward on manual valve levers. Properly adjusted, the gauge will be held in place horizontally without being supported.
5. If readjustment is required, loosen lock screw, Fig. 5, push manual valve levers forward so that gauge is held in position. Retighten lock screw.

1961 Throttle Linkage

The location of the throttle return spring shown in Fig. 6 has been changed to the position illustrated in Fig. 7. Therefore, the following procedure supersedes that which is given in the 1961 Edition. Failure to adjust linkage properly will result in poor unloader operation of carburetor and only partially wide open throttle operation. To adjust, proceed as follows, referring to Figs. 6 to 8.

1. Insert ¼″ gauge pin in hole in block just forward of pivot point of throttle control lever.
2. Adjust carburetor throttle control rod to give a wide open throttle when throttle control lever upper surface is against the pin. *When adjusted, remove gauge pin.*
3. Check height of accelerator pedal stop. This should be $1\frac{11}{16}$″ to toe pan. If not, loosen lock nut and reset to correct height.
4. Install .060″ shim on top of pedal stop (a penny and masking tape makes a good shim).
5. Hold or block accelerator pedal against shim and pedal stop (wide open throttle position).
6. Adjust trunnion on T.V. rod to position transmission T.V. lever against wide open throttle stop in transmission. *There is a definite stop in transmission which should not be confused with resistance encountered at the detent.*

Fig. 8 Throttle linkage. 1961 V8

Fig. 8A Four cylinder throttle linkage. 1962

7. Adjust trunnion on throttle control rod to hold carburetor in wide open position. Tighten trunnion nuts.
8. With accelerator pedal held against shim and pedal stop, check to be sure that carburetor and transmission T.V. lever have a wide open throttle at the same time.
9. Remove pedal shim. Then, with engine running, slowly move selector

Fig. 8B Throttle linkage. 1962 V8

Fig. 8C Pressure tap locations

lever to "L" position. If engine speed increases, linkage is not properly adjusted.

1962

1. Disconnect throttle valve cable at carburetor throttle lever, Figs. 8A and 8B.
2. Block carburetor in wide open throttle position.
3. Pull throttle valve cable fully forward until T.V. lever is against stop in transmission. *Do not confuse transmission detent feel with lever stop contact.*
4. Adjust position of front connector at trunnion so it may be slipped freely into carburetor adapter lever. Tighten lock nuts.
5. Recheck adjustment after connecting cable by holding carburetor at wide open throttle position and checking to be sure T.V. lever is against stop. *Do not adjust cable more than two turns of trunnion from standard position. If shift points are not as desired, perform T.V. pressure check and adjust as outlined further on.*

Low Band, Adjust

No periodic adjustment of the band is recommended. However, if necessary it may be adjusted as follows:

The transmission must be lowered to gain access to the adjusting screw. To adjust, loosen lock nut and tighten adjusting screw to 35-45 inch lbs. torque, then back off 4 full turns exactly. While holding screw, tighten lock nut securely.

TROUBLE SHOOTING

Hydraulic Pressure Tests

Two pressure tap plugs in the extension housing are shown in Fig. 8C. All tests can be made without driving the vehicle by simply raising the wheels 3 to 5 inches from the floor on jack stands. With pressure gauges installed, perform the following preliminary steps:

1. Pressure gauge needles should be at zero pressure.
2. Thoroughly warm up transmission.
3. Check transmission oil level.
4. Check linkage adjustment.

FRONT PUMP PRESSURES (PSI)

CONDITION	Eng. Type	R	N	D	L
At Idle (16" Hg)	4 Cyl.	106-130	55-67	55-67	124-137
	8 Cyl.	110-139	59-73	59-73	130-151
At 1000 RPM with Vacuum Hose Disconnected	4 Cyl.	198-222	101-114	101-114	124-137
	8 Cyl.	202-231	105-120	105-120	130-151

THROTTLE VALVE (TV) PRESSURE (PSI)

CONDITION	Eng. Type	R	N	D	L
Disconnect TV cable at Transmission and Vacuum Hose at Modulator. Hold TV Lever forward against stop— Engine at 1000 RPM	4 Cyl.	0	0	50-52	119-132
	8 Cyl.	0	0	48-50	125-146

Fig. 8D Oil pressure charts

Front Pump Check, Fig. 8D

Absence of front pump pressures results in no drive in any range as this pressure is required to apply the applicable clutch for a given range. Common causes would be stuck pressure regulator valve, broken or disengaged front pump drive lugs, or missing plug from front end of converter pump shaft.

Failure of pressure to raise when disconnecting the vacuum hose (or high pressures with hose connected) would indicate a stuck vacuum modulator valve, defective vacuum modulator, or collapsed hose.

Rear Pump Checks

With wheels raised, place selector lever in "D" and accelerate engine. Front pump pressure should drop to 0 to 5 psi at about 20 mph. If pressure does not drop, rear pump is disengaged or clogged, or rear pump ball check is not seating.

Throttle Valve (TV) Pressure

Throttle valve pressure tests are of value in cases where the shift points are not in accordance with the data listed below. If pressures are not as prescribed, they may be raised or lowered by adjusting the position of the jam nut on the throttle valve, Fig. 5.

To raise the pressure 3 psi, back off the jam nut one full turn. This increases the dimension from the jam nut to the throttle valve stop. Conversely, tightening the jam nut one full turn lowers the pressure 3 psi. Smaller pressure adjustments can be made by partial turns on the jam nut. The end of the TV adjusting screw has an Allen head so the screw may be held stationary while the jam nut is moved.

Throttle Pressures, Fig. 8D

Disconnect throttle valve rod at carburetor and hose at vacuum modulator. Depress accelerator pedal to wide open position. By disconnecting rod engine remains at idle speed throughout test.

In Car Repairs

EXTENSION OIL SEAL

1. Remove torque tube and propeller shaft as outlined in the *Rear Axle Section.*
2. Pry out old oil seal and tap new seal into position.
3. Install torque tube and propeller shaft.

EXTENSION BEARINGS

1. Remove torque tube and propeller shaft as directed in *Rear Axle Section.*
2. Remove oil seal and bearing snap ring.
3. Insert tool in extension housing, Fig. 9, so that it picks up inner race of bearing.
4. Using slide hammer as shown, tap out front bearing, spacer sleeve and rear bearing.
5. Using suitable socket, tap new rear bearing into position. Install spacer sleeve and tap in new front bearing.
6. Install new oil seal, torque tube and propeller shaft.

VACUUM MODULATOR

1. Referring to Fig. 10, remove hose and unscrew vacuum modulator, using lock pick pliers or a thin 1" wrench. Remove valve from transmission.
2. Check valve for nicks or burrs; if such cannot be repaired with a slip stone, replace valve. *The modulator can be checked with a vacuum source for leakage. However, leakage normally results in transmission oil pull-over, oil smoky exhaust and continually low transmission oil.* If defective, install a new modulator.
3. When installing the new modulator, coat gasket with vaseline and hold it centered during installation to prevent transmission external oil leak.

Fig. 10 Location of vacuum modulator

Fig. 9 Removing extension housing bearings

GOVERNOR

Referring to Fig. 11, remove lock screw securing governor tab to case and pull governor from transmission.

The only part replaceable is the driven gear. To remove, drive out roll pin with a punch and pull out old gear. Drill a new hole in the governor 90° from the original, insert new gear and install roll pin.

To install, use O-ring on governor and install governor into transmission with a slight twist to engage gear teeth. Secure with lock bolt.

VALVE BODY & LOW SERVO

1. To remove valve body, loosen oil filler nut in order to drain transmission oil and remove filler pipe.
2. Disconnect throttle valve rods from transmission levers.
3. Remove oil pan and gasket.
4. Remove retainer screw, oil screen and O-ring.
5. Loosely install retainer, Fig. 12, in pan screw hole. Retainer can be made from a piece of sheet metal.
6. Remove valve body attaching screws and tap valve body lightly to loosen from its dowels; then carefully lower body about $\frac{1}{16}$". Rotate retainer into place so it secures servo piston hub and tighten with oil pan screw. This eliminates the possibility of servo piston slipping out of its bore and loss of low band engagement with its apply components.
7. Remove valve body and gasket.
8. If necessary, remove downshift timing valve and install a new one, Fig. 12.
9. If necessary to remove low servo,

Fig. 11 Transaxle assembly

tighten low band adjusting screw fully. Remove retainer and pull downward on piston shaft with screwdriver.

10. If necessary, replace front pump air bleed valve as shown in Fig. 13.
11. When disassembling the valve body the modulator body should be held during removal of screws as it is under spring pressure from pressure regulator valve spring.

Valve Body, Inspect & Assemble

As most valve body failures are initially caused by dirt or other foreign matter preventing a valve from functioning properly, a thorough cleaning of all parts in clean solvent is mandatory. Check all valves and their operating bores for burrs or other deformities which could result in valve "hang-up".

Assemble the valve body in reverse order of disassembly, referring to Fig. 14 as a guide.

Low Servo Repairs

To disassemble the low servo piston, remove the hairpin retainer securing the piston to the piston rod and separate parts. The cushion spring tension on this piston is relatively light; no press is required.

Remove ring from piston and install it in the low servo bore and measure the ring gap. If within limits ring gap will be .002" to .012".

Assemble ring to piston. Measure clearance between ring and one wall of piston groove. Clearance should be .0005" to .005".

To assemble low servo, place spring seat on piston shaft. Install cushion spring. Complete assembly by compressing cushion spring slightly with piston and secure piston to shaft with hairpin retainer.

Fig. 12 Servo piston retainer, downshift timing valve

Fig. 14 Valve body parts layout

Valve Body & Low Servo, Install

1. Install low servo piston and return spring in transmission bore and engage notch in piston shaft with low band apply strut, loosening low band screw slightly to permit piston ring to seat in case bore and allow installation of valve body.
2. Install retainer to hold servo piston in bore (see Fig. 12).
3. Position new gasket on valve body.
4. Position valve body in transmission, indexing on dowels and remove retainer. Be sure manual valve indexes properly with pin on inner shaft lever.
5. Secure valve body with 20 screws and tighten them to 9-11 ft. lbs.
6. Install oil pick-up screen and O-ring in valve body and secure with screw.
7. Position manual valve lever in full reverse position so it is held securely by wedging device in transfer plate. Engage shift control cable and secure.
8. Using a new oil pan gasket, install oil pan and torque bolts to 3-4 ft lbs. It is important that an even torque be applied to the pan bolts to prevent leakage between pan and pan rail.
9. Tighten filler tube attaching nut; then refill transmission with oil.
10. Readjust band as previously directed.

Fig. 13 Front pump air bleed ball

Repairs Requiring Transmission Removal

TRANSMISSION, REPLACE

The procedure for removing and replacing the transmission is covered in the *Rear Axle Section.*

TRANSMISSION, DISASSEMBLE

1. Remove converter. Reinstall cap on converter after removal and place cap side down to retain oil.
2. Remove speedometer driven gear.
3. Remove governor and O-ring.
4. Remove turbine drive shaft.
5. Unfasten and separate transmission from differential carrier.
6. Remove vacuum modulator and valve.
7. Loosen low band adjusting screw jam nut and fully tighten adjusting screw.
8. Remove 12 housing attaching screws.
9. Tap off extension housing.
10. Remove thrust washer and coupling, Fig. 15. Remove converter pump drive shaft, Fig. 16. It is not necessary to remove drive key unless it is to be replaced.
11. Remove thrust washer from pump body.
12. Remove pump gears. Stack so they may be reassembled with same face up.
13. Remove pump body and gasket.
14. Remove pump body-to-clutch drum thrust washer.
15. Loosen low band adjusting screw and remove low band, apply strut and reaction strut, Fig. 17.
16. Remove clutch drum assembly.
17. Remove clutch drum-to-sun gear thrust washer (1961) or needle bearing (1962), Fig. 18.
18. Remove planet carrier from ring gear.

Fig. 15 Thrust washer and coupling

Fig. 16 Converter pump shaft

19. Remove ring gear from engagement with reverse clutch plates.
20. Remove clip mounted on thick reverse reaction plate between ends of reverse clutch snap ring and remove snap ring, Fig. 19.
21. Remove thick reverse reaction plate, three drive plates (faced) and three reaction plates (steel).
22. Remove rear pump and reverse piston mounting bolts at rear of case.
23. Remove rear pump and reverse piston assembly.
24. Remove rear pump wear plate.

UNIT REPAIRS

Rear Pump & Reverse Piston

1. To disassemble, remove drive and driven gears. Stack so they may be reassembled with same face up.
2. Compress spring retainer, Fig. 20. With retainer compressed until springs bottom, remove snap ring. Carefully release pressure and remove retainer and springs.
3. In order to remove reverse piston, it is necessary to fill snap ring groove in hub of body with string, a small rubber band or a similar size O-ring. Once groove is filled, pump body can be pushed out of piston bore.
4. Remove square cut piston inner seal and piston outer seal. Discard and install new seals at reassembly.

Inspection

1. With all parts clean and dry, check fit of pump gears. Clearance between OD of driven gear and body should be .0025-.005″. Clearance between driven gear and crescent should be .003-.009″. Gear end clearance, checked with feeler gauge and straight edge, should be .0005-.0015″.
2. Inspect pump body for leaks and scoring. Check hub of pump body for smoothness. *Any burrs on this surface would cause leakage and could result in a jammed reverse piston.*
3. Check for broken piston return springs and make a comparative check of spring heights by standing all springs in a row. If appreciable variance in spring height is noticed, replace springs.
4. If pump body bushing is scored or worn, replace bushing.

Assemble

1. Install piston inner seal in reverse piston, Fig. 21.
2. Install piston outer seal in piston with lip of seal toward pump body.
3. Install piston on pump body.
4. Position 17 return springs in their seats on piston, then replace spring retainer on springs.
5. Compress springs as shown in Fig. 20. With springs fully depressed, install snap ring in groove in pump body.
6. Complete assembly by installing drive and driven gears in body. It is advisable to apply a small amount of vaseline to gears to prevent their being dropped from pump body.

Clutch Drum

1. To disassemble, remove retainer ring securing low sun gear and clutch flange to clutch drum. Remove thrust washer.
2. Lift out clutch hub, then remove drive and driven plates and hub thrust washer.
3. To remove spring retainer, compress springs, Fig. 22, and remove snap ring.

Fig. 17 Location of apply and reaction struts

Fig. 18 Sun gear thrust washer (1961) or needle bearing (1962)

Fig. 23 Clutch drum components

Fig. 19 Reverse snap ring retaining clip installed

Fig. 20 Compressing reverse piston springs

Fig. 21 Rear pump and reverse piston components

4. Carefully release pressure and remove retainer and springs.
5. To remove clutch piston, pull upward with a twisting motion on center. Then remove piston seal.
6. Remove piston inner seal from hub of clutch drum.

Inspection

1. Wash and air dry parts, Fig. 23.
2. Inspect drum band surface for excessive scoring or burning. Also check and, if necessary, replace drum bushing if scored or worn.
3. Check steel ball in drum that acts as a relief valve, Fig. 24. Be sure that it is free to move in hole and that orifice leading to front of drum is open. If clutch relief valve check ball in drum is loose enough to come out or not loose enough to rattle, replace drum as an assembly. *Replacement or staking of ball should not be attempted.*
4. Check fit of clutch flange in drum slots. There should be no appreciable radial play between these two parts. Also check low sun gear for nicks or burrs and bushing for wear.
5. Check clutch plates for burning, pitting or metal pick up. Also check to see that faced plates are a free fit over clutch hub and that steel plates are a free fit in clutch flange. Check for excessive wear on friction facing of drive plate teeth. Check condition of clutch hub splines and mating splines on faced plates.

Assemble

1. Install piston inner seal in hub of drum. Be sure seal lips are downward (toward front of transmission).
2. Install new piston seal in clutch piston, being sure seal lips are toward front of transmission. Lubricate seals and install piston in drum with a twisting motion.
3. Place 15 return springs on piston. Place spring retainer on springs. Compress springs, Fig. 22. With springs fully compressed, install snap ring in groove on clutch drum hub.
4. Install hub front thrust washer with its lip toward drum. Install clutch hub.

Fig. 22 Compressing clutch springs

5. Install steel reaction plate, faced plate, two steel plates, then steel plate.
6. Install hub rear thrust washer with its flange toward low sun gear, then install sun gear and clutch flange and secure with retainer ring. Openings of retainer ring should be adjacent to one of the lands of clutch drum.
7. Check assembly by turning clutch hub to insure it is free to rotate.

Fig. 24 Relief check ball

Fig. 25 Extension housing and related parts

Fig. 26 Rear pump and reverse piston

Fig. 27 Reverse clutch reaction plates

Fig. 28 Zeroing dial indicator on planet carrier hub

Front Pump & Extension Housing

1. To disassemble, pry out oil seal and remove bearing retainer ring, Fig. 25.
2. Invert extension housing. Using a suitable socket as a driver, tap out front bearing, spacer sleeve and rear bearing.

Inspection

1. Wash all parts and blow out oil passages.
2. Inspect pump gears, cover face and body for nicks or scoring.
3. Check oil control rings on body.
4. Check condition of bushing in body and replace if necessary.
5. Install pump gear and check clearance between OD of driven gear and body which should be .0025-.005″. Clearance between driven gear and crescent should be .0025-.005″. With scale and feeler gauge, check clearance between gears and cover face which should be .0005-0015″.

Assemble—Install parts in extension housing as shown in Fig. 25. Use suitable socket to install bearings. Do not tap on inner races. Install snap ring and oil seal. Install square cut oil ring on OD of pump cover.

Planet Carrier Service Note

The bronze sun gear thrust washer located in the planet carrier assembly was replaced in February 1961 by a needle thrust bearing, see Fig. 18. The bearing can easily be identified by the fact that it is thicker than the thrust washer and its increased diameter makes it non-removable from the carrier assembly. Production transmissions containing these new parts can be identified by a daub of blue paint on the outside of the transmission case. To accomodate this change, it was necessary to use a new clutch flange, a new low sun gear assembly and a new turbine shaft assembly.

The early type carrier assembly, thrust washer, turbine shaft and low sun gear flange are not serviced. If it is necessary to replace one of these components for any reason on an early type transmission, it will be necessary to install the new low sun gear thrust washer repair package. This package consists of a planet carrier assembly, turbine shaft assembly, and low sun gear flange assembly.

Turbine and Pump Drive Shafts and Converter

1. Inspect splined areas of turbine shaft for wear or damage. Check oil holes to be sure they are open. Inspect bushings for wear or damage; if damaged, replace.
2. Inspect splines of pump drive shaft for wear or damage. Inspect drive lugs for wear or peened edges.
3. It is unnecessary to drain converter as it is welded and no internal repairs can be made. Check converter seams for stress or breaks and either replace converter or repair welds as required. If welds are repaired, keep added material to a minimum by chipping off scale and filing away excess weld to retain converter balance. Check converter hub bushing for wear or damage.

Fig. 29 Measuring for shim determination

TRANSMISSION, ASSEMBLE

1. Install two guide pins in rear pump bolt holes, then install rear pump wear plate on guide pins, using small amount of vaseline to hold wear plate in place.
2. Insert rear pump and reverse piston with guide pins into case, Fig. 26. Insert a length of .010-.015″ shim stock between piston outer seal and case. Run shim around entire diameter of seal to seat seal. Remove guide pins and install five pump mounting bolts and tighten to 9-11 ft. lbs. Check rear pump for freeness before proceeding.
3. Install reverse clutch drive and reaction plates alternately starting with a steel plate and finishing with a faced plate. Notched lug in each steel plate is installed so it is at top of groove at 4 o'clock position in case, Fig. 27. Install thick reaction plate. It has rectangular "dimple" on its lug which engages 4 o'clock case groove.
4. Install reverse clutch plate retainer ring in such a manner that open ends of ring are at 12 o'clock position, then install retainer ring clip on thick reaction plate between ends of snap ring.
5. With rear of case downward, align internal lands and grooves of reverse face plates.
6. Engage ring gear to reverse drive plates. Engagement must be made by "feel" while moving drive plates laterally.
7. Install planetary unit with a slight twist to engage planet gears with ring gear. Be sure to engage two rear pump drive lugs on planet hub with grooves in rear pump drive gear.
8. Install thrust washer on captive input sun gear in planetary gear set with flange of thrust washer toward front of transmission. If necessary,

Indicator Reading	Spacer No. 6256827	
	Number	Thickness
.025 - .046	None	—
.047 - .062	1	.016 ± .001
.063 - .078	2	.032 ± .002
.079 - .094	3	.048 ± .003
.095 - 110	4	.064 ± .004
.111 - .126	5	.080 ± .005
.127 - .142	6	.096 ± .006
.143 - .155	7	.112 ± .007

Fig. 30 Spacer chart

apply a small amount of vaseline to keep washer centered.

9. Install clutch drum assembly, using a slight twist to engage low sun gear to planet gears in planetary gear set.
10. Turn transmission to a horizontal position, then install low band, apply strut and reaction strut. When low band linkage is installed, tighten low band adjusting screw to prevent struts from falling out of place. Then shake clutch drum slightly to center band and linkage.
11. Replace original thrust washer or new washer of same size if original is damaged. Final end play adjustment will be performed at governor drive gear prior to assembly of transmission to differential carrier.
12. Install new front pump gasket. Then install pump body, being careful not to break cast iron oil rings on pump body hub when they are indexed to clutch drum.
13. Install inner and outer pump gears with drive notches on inner gear facing up, and outer gear with same face up as removed.
14. Install thrust washer in pump body.
15. Install converter pump drive shaft. Use care when inserting pump shaft not to damage bushings of transmission components already installed.
16. Position coupling on end of pump drive shaft.
17. Position coupling thrust washer in extension housing .Washer is retained by light press fit.
18. Install a new square cut seal ring in extension housing. Position extension housing. Dip bolt heads in oil impervious sealer and install bolts loosely. Tighten outer bolts in criss-cross pattern to 15-20 ft. lbs. Then tighten inner bolts to the same torque. By using this sequence, chance of cocking front pump, which would bind pump, is virtually eliminated. Check pump for freeness before proceeding.
19. Adjust low band by first tightening adjusting screw to 40 inch lbs., then back off four full turns exactly. Hold adjusting screw and tighten lock nut.

TRANS. TO DIFF. CARRIER, ASSEMBLE

1. Prior to reassembly of carrier and transmission it is necessary to determine required thickness of shim pack to be installed at front face of governor drive gear.
2. To do this, mount a dial indicator as shown in Fig. 28. Without gasket, place support on rear pump cavity surface as shown so that dial indicator tip rests on planet carrier hub. Adjust indicator to permit maximum indicator travel and set indicator dial to zero. Front end of transmission must face downward when indicator is zeroed.
3. Slowly lift support and indicator off rear pump cavity and note its range of needle deflection from zero position. Properly positioned on support, indicator should not deflect more than .050″ (one-half turn) when removed; otherwise raise or lower indicator on support post as required and again zero gauge.
4. Place gauge and support on governor gear without spacers on differential pinion shaft as shown in Fig. 29, and lower slowly so that revolutions of needle can be counted. Measurement starts once indicator needle again reaches zero. Fully depress support on governor gear, note reading and refer to chart, Fig. 30, for spacers to be installed on governor gear.

Fig. 31 Installing spacers

5. Install spacers selected on governor gear, Fig. 31, then check that proper total thickness has been installed by again measuring. If shim stack is correct, dial reading will now be .025-.038″; otherwise add or remove spacers until reading is within this range.
6. Apply a new gasket to transmission or carrier face. Align carrier and transmission on a flat surface and carefully guide pump shaft through differential carrier so as not to damage bushing in pinion. Then engage splines of pinion shaft with planet carrier internal splines in transmission.
7. Install governor and O-ring seal and secure transmission to carrier with four screws. Drive two screws from carrier side first to minimize chance of cocking mating surfaces. Tighten screws to 30-35 ft. lbs.
8. Install turbine shaft into converter and then install converter and turbine shaft, using care not to damage turbine shaft bushings when sliding over converter pump shaft. It is necessary to use caution in engaging splines in converter and at end of turbine shaft. Do not force.

Rear Axle, Propeller Shaft & Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

DESCRIPTION

The differential and carrier assembly is a component of the transmission and differential assembly, Fig. 1. This design combines the two and is commonly referred to as a transaxle. The differential and carrier design utilizes a hypoid ring and drive pinion set with the pinion shaft above the center of the ring gear. The remaining components of the unit are conventional. The assembly is mounted on the rear suspension crossmember and is sprung with the body weight.

Each axle shaft is independently suspended and is free to move in a vertical plane in an arc. The axle shaft is attached to universal joints which in turn are splined into the differential side gears. The driving force is transmitted by the lower control arm and lateral forces are absorbed by self-aligning wheel bearings and rubber bushings at the lower control arm attachment to the rear crossmember.

The differential and carrier assembly

used with both the manual shift and automatic transmissions are identical except for the drive pinion shaft, front pinion bearing adjustment nut, rear pinion bearing retainer, and oil seals.

The manual shift transmission drive pinion shaft is hollow and is splined internally to receive the transmission mainshaft. The drive pinion shaft used with the automatic transmission is also hollow but is splined externally so that the drive pinion shaft may be inserted in the transmission planet carrier hub. With automatic transmission, the turbine shaft passes through the drive pinion shaft to connect the turbine to the transmission. Details of the propeller shaft and torque tube are shown in Fig. 2.

AXLE SHAFT

1. Remove wheel and brake drum.
2. Through hole in axle shaft flange, remove four nuts securing axle bearing retainer to brake backing plate.
3. Pull brake backing plate outward slightly, then push it back on the control arm studs to break backing plate away from bearing retainer.
4. Remove four nuts and lock tabs from U-bolts attaching universal to axle flange.
5. Pull axle shaft outward enough to separate flange from U-bolts.
6. Remove flange from shaft.
7. Remove axle shaft from lower control arm. Replace bearing if necessary.

Installation

1. Insert shaft through lower control arm. Install flange on axle shaft splines. It may be necessary to tap flange onto splines if original parts are being installed.
2. Attach universal to flange on axle shaft. *Tighten U-bolts to 14-20 ft. lbs. Also be sure universal joint snap rings are properly installed.*
3. With bearing retainer and brake backing plate holes aligned with control arm studs, insert universal splined yoke through seal at side bearing and index with splines of side gears. Coat lip of seal and splines with hypoid oil to help prevent damage to seal from splines of universal yoke.
4. Secure bearing retainer to backing plate and torque nuts to 30-45 ft. lbs.
5. Install brake drum and wheel.

Fig. 2 Propeller shaft and torque tube. Late 1961 and 1962 do not have damper bolts at each side of intermediate propeller shaft bearings

Fig. 1 Differential and carrier assembly

PROP. SHAFT & TORQUE TUBE

Manual Shift Trans.

1. On early 1961 models, remove propeller shaft damper bearing bolts, Fig. 3.
2. Remove parking brake cable from torque tube.
3. Disconnect exhaust system at engine and slide off entire system.
4. Remove gearshift housing.
5. Remove flywheel housing lower cover.
6. Remove torque tube access hole cover.
7. Remove propeller shaft flange bolts.
8. Place a short piece of rubber hose or rag between propeller shaft and torque tube.
9. Unfasten torque tube from flywheel housing.

Fig. 3 Removing propeller shaft damper bearing bolts. Early 1961

10. Pry torque tube and propeller shaft away and down from flywheel housing.
11. Place block of wood 2″ square between transmission extension and floor of car to position transmission for reassembly. Support torque tube with stand.
12. Unfasten torque tube from transmission. Remove propeller shaft and torque tube as a unit by pulling on propeller shaft flange.
13. Pull propeller shaft out of torque tube, being sure not to pull insulator and bearing over sleeves, Fig. 4. *Extreme care should be exercised not to damage the coating on propeller shaft. Damage to this coating will shorten the life of the drive line.*

Installation Notes

Reverse removal procedure to install, being sure to observe the following:

Assemble propeller shaft in torque tube and place a short piece of rubber hose of rag between front of propeller shaft and torque tube *so that coating on propeller shaft will not be damaged.*

When installing shaft in torque tube, the shaft should enter without using force. Extreme care should be exercised not to damage the coating on propeller shaft as damage to this coating will shorten the life of the drive line.

Coat spline generously with axle lube and use care when entering shaft into extension seal. Never allow weight of shaft to rest on seal.

When installing shaft into transmission, be sure to engage spline of shaft into transmission and journal diameter into transmission extension bearings so as not to damage journal surface. Visual check of propeller shaft alignment into transmission extension is required, and if absolutely necessary, tap front flange lightly with a soft rubber hammer. Be sure splines are completely engaged in transmission.

Tighten torque tube to transmission extension bolts to 30-45 ft. lbs. torque. Torque bolts securing propeller shaft flange to clutch drive shaft to 30-45 ft. lbs.

Automatic Transmission

1. On early 1961, remove propeller shaft damper bearing bolts, Fig. 3.
2. Remove parking brake cable and vacuum line from torque tube.
3. Remove stabilizer bar.
4. Disconnect at engine and slide entire exhaust system off.
5. Remove flywheel housing lower cover.
6. Disconnect propeller shaft flange from flywheel.
7. Loosen half way the bolts that connect torque tube to flywheel housing.
8. Place a short piece of rubber hose or rag between propeller shaft and torque tube to prevent damage to coating on drive line.
9. Using a screwdriver, pry propeller shaft flange to rear far enough for pilot to clear recess in flywheel.
10. Disconnect torque tube from flywheel housing.
11. Pull shaft and torque tube down and away from flywheel housing.
12. Place a 2″ square block of wood between transmission and floor of car to position transmission extension for reassembly.
13. Support torque tube and unfasten it from transmission. Remove propeller shaft and torque tube as a unit by pulling on propeller shaft flange.
14. Pull propeller shaft out of torque tube, do so without using force. Use extreme care not to damage coating on propeller shaft as damage to this coating will shorten the life of the drive line.

Installation Notes

Reverse removal procedure to install the propeller shaft and torque tube, observing the precautions outlined for cars with manual shift transmission.

Fig. 4 Spreading torque tube with flat drift if propeller shaft will not come out of torque tube easily. Early 1961

TRANSAXLE, REPLACE

Early 1961

1. Raise car and support transaxle.
2. Drain lubricant from differential and manual shift transmission, or fluid from automatic transmission.
3. Support rear of engine with stand.
4. Remove wheels and brake drums.
5. Unfasten bearing retainer from backing plate.
6. Pull axle shafts out far enough to remove universal from differential carrier.
7. Remove propeller shaft damper bearing bolts, Fig. 3.
8. Remove speedometer driven gear.
9. On manual transmission, disconnect control rod from transmission and parking brake cable from torque tube. Remove gearshift lever housing.
10. On automatic transmission, disconnect TV rod and manual valve cable from transmission. Remove vacuum line and parking brake cable from torque tube.
11. On V8's, remove exhaust crossover pipe.
12. Remove flywheel cover from engine.
13. On manual shift jobs, remove torque tube access cover.
14. Unfasten propeller shaft flange from clutch drive extension (manual shift) or flywheel (automatic). Place a rag between front of propeller shaft and torque tube to prevent damage to coating on propeller shaft.
15. Unfasten torque tube from flywheel housing.
16. Through access holes in trunk floor or from under car, remove two bolts securing transaxle to rear crossmember. Remove bolts from bracket.
17. Lower complete transaxle and torque tube from car.
18. Reverse removal procedure to install the assembly, observing the precautions mentioned in the procedure under *Propeller Shaft and Torque Tube.*

Late 1961 and 1962

1. Raise car so that rear wheels hang free. Support torque tube and transaxle separately. Drain lube from transaxle.
2. Remove rear wheels and brake drums.
3. Remove bolts securing axle shaft bearing retainer to brake backing plate. Pull axle shafts out far enough to remove U-joint flanges from differential carrier.
4. On manual transmission jobs, disconnect speedometer cable and parking brake spring from differential carrier. On automatic transmission cars, disconnect vacuum line, parking brake return spring, T.V. rod, transmission control cable and speedometer cable. Remove oil filler tube.
5. Disconnect torque tube from transmission extension.
6. Unfasten differential carrier from rear crossmember. Remove bolt from bracket.

Fig. 5 Differential and carrier components. When used with four speed manual shift transmission a four-pinion differential is used

7. On manual transmission cars, remove muffler support bracket from torque tube.
8. Separate transaxle from torque tube and lower transaxle from car.
9. To install, reverse removal procedure.

DIFF. CARRIER

1. Separate differential and transmission, Fig. 5.
2. On A.T. jobs, pull off governor drive gear and spacers.
3. Remove differential side bearing oil seals (if the occasion arises, these seals may be replaced without taking assembly for car).
4. Remove side cover and lift out differential case and ring gear.
5. In order to provide complete diagnosis, check tooth pattern with red or white lead as outlined in *Rear Axle* chapter.
6. Remove pinion rear bearing retainer and shim pack. On A.T. jobs only, remove rubber oil passage seal. Tap retainer out from front of case if necessary.
7. Remove front pinion bearing adjusting nut lock and nut.
8. Remove drive pinion.
9. Remove side bearing adjusting nut lock screw and nut.
10. Remove side bearing race. If difficult to remove, screw in adjusting nut until race is pushed out into carrier housing. Remove adjusting nut.
11. Remove drain and filler plugs.
12. Remove adjusting nut lock screw, nut, bearing race and O-ring seal from side cover.

Diff. Case and Ring Gear

1. If side bearings or case is to be replaced, remove bearings.
2. A mark is scribed across parting line of case and cover to aid in alignment on reassembly.
3. Remove 8 ring gear bolts.
4. Reinstall two bolts partially in ring gear and tap ring gear off case.
5. Separate cover and case. Remove side gear and thrust washer from cover half. Drive out roll pin which retains cross shaft and drive out cross shaft.
6. Remove pinions, thrust washers and side gear from case.
7. Reassemble in reverse order and tighten ring gear bolts to 55-65 ft. lbs.

Fig. 6 Determining drive pinion shim thickness required

Drive Pinion

1. On A.T. jobs, remove oil ring from pinion shaft.
2. Remove front pinion bearing.
3. Press off speedometer gear.
4. Press off rear bearing.
5. Place rear pinion bearing in its retainer. Place tool (J-8919) on retainer as shown, Fig. 6. Use feeler gauge as shown to determine correct shim thickness required on reassembly. Use chart, Fig. 7, to convert feeler gauge readings to shim specifications. If pinion shaft is marked, use chart, Fig. 8, for correction. *If bearing race is to be replaced, do so before determining shim requirements.*

Fig. 7 Drive pinion shim chart

6. Press on rear bearing, speedometer drive gear and front bearing. On A.T. jobs, replace oil ring.

Assemble and Adjust Differential and Carrier

1. Install side bearing race in carrier casting.
2. Start side bearing adjusting nut.
3. Position side bearing race in side cover and start side bearing adjusting nut.
4. Position ring gear and differential case in carrier.
5. With oil seal removed, place side cover on case with four bolts. Be sure two aligning bolts are in correct holes.
6. Turn side bearing nut in cover finger tight.
7. Install tool, Fig. 9, in end of differential cross shaft through side cover.
8. Adjust side bearing preload to 10-20 inch lbs. by turning adjusting nut in carrier. Check preload as shown.
9. Install adjusting nut lock screws and washers.
10. Remove tool, Fig. 9, from shaft and remove side cover from carrier, and case and ring gear from carrier housing.
11. Install shim pack as already determined. Install new rubber oil passage seal (A.T. only). Install new O-ring seal on rear pinion bearing retainer. Install retainer on housing (8 bolts).
12. Invert carrier and position pinion shaft in carrier. Install pinion adjusting nut (also O-ring seal on A.T. jobs). Tighten nut until play of pinion shaft is eliminated.
13. Install tool, Fig. 10, inside pinion shaft and tighten nut.
14. Adjust pinion bearing preload to 10-16 inch lbs., Fig. 11.
15. Check tooth pattern as described in *Rear Axle* chapter.
16. Place ring gear and differential in carrier. Install side cover without O-ring seal and retain with four bolts. Remove side bearing adjusting nut lock screws.
17. Install tools as shown in Fig. 12. Dial indicator should rest squarely on line scribed on handle of J-8903.
18. Insert large screwdriver in other end of differential shaft.
19. Adjust ring gear and pinion backlash to .004-.009″ by loosening one adjusting nut and tightening the other one notch at a time (do not rotate pinion). Move ring gear toward pinion to decrease backlash and away from pinion to increase backlash. Remove tools except J-8903.
20. Reinstall side bearing adjusting nut lock screws (10-20 inch lbs. torque).
21. Rotate pinion shaft clockwise 4 turns and counterclockwise 4 turns while creating a drag on tool J-8903, Fig. 12.
22. Remove side cover and ring gear.
23. Analyze tooth patterns and make necessary corrections. *Any change in shim pack will require new pinion bearing preload and side bearing backlash adjustments.* If no corrections are necessary proceed with reassembly.
24. Reinstall ring gear and differential. Install side cover, using new O-ring seal. Tighten side cover bolts to 10-20 ft. lbs. Apply bead of sealer and

PINION CORRECTION CHART	
MARK	CORRECTION TO BE APPLIED TO SHIM STACK WHEN PINION IS MARKED
-4	ADD .004 TO SHIM STACK

+4	SUBTRACT .004 FROM SHIM STACK

Fig. 8 Drive pinion correction chart

Fig. 9 Checking side bearing preload

Fig. 10 Tool installed in pinion shaft

Fig. 11 Adjusting pinion bearing preload

Fig. 12 Tools in position for adjusting backlash

install new side bearing oil seals. Install drain and filler plugs.

25. Install governor drive gear and spacers on A.T. jobs as outlined in Transmission Section.
26. Assemble transmission and differential carrier.

MASTER CYLINDER

1. To remove, disconnect brake pedal return spring. Disconnect master cylinder push rod from brake pedal.
2. Remove hydraulic line from master cylinder. Unfasten cylinder from cowl and lift off.
3. Reverse removal procedure to install master cylinder. Bleed brake system as outlined in *Hydraulic Brakes* chapter.

Suspension & Steering Section

FRONT SUSPENSION

As shown in Fig. 1, stamped steel suspension control arms are used with rubber bushed mounting shafts. A strut bolted to the lower control arm is mounted at the rear with rubber bushings while the inner end is threaded so that the front suspension caster angle may be readily adjusted by varying the effective length of the strut. The coil springs are seated on the lower control arm and the shock absorbers operate within the coils. To completely isolate the body from road noise, the tops of the springs are seated against rubber insulators. Half ball joints with phenolic seats and anti-dive suspension geometry are also features of this system.

REAR SUSPENSION

As shown in Fig. 2, the swing axle independent rear suspension provides independent action of each rear wheel and reduced unsprung weight as well as positive control of suspension geometry. In this system a rear crossmember is attached to the integral body in four positions. Attached to the rear crossmember is the transaxle support mounted in rubber for noise and vibration isolation. This is in turn affixed to the differential in a manner to provide fore and aft shimming for toe variation.

The swing axle suspension gets its name from the fact that suspension travel is provided by allowing each wheel to swing through arcs of radius equal to the axle shaft length. Because the rear wheels are independently suspended, new geometry factors must be considered. Wheel camber, for example, is designed to change as the suspension moves up or down from the design height position. Since the outside wheels carry the greatest weight in a turn, camber characteristics of the rear suspension create desirable understeer geometry.

SUPENSION ADJUSTMENTS

Front Wheel Bearings

1. Remove dust cap.
2. Check for slip fit of bearing cones on spindles. Bores of bearing cones should have a light coat of wheel bearing lubricant to allow cones to creep on spindle.
3. If nuts turn hard on spindle, check for and remove any burrs from spindle threads.
4. With tire off ground, and while rotating it in both directions, tighten nut with torque wrench to 10-20 ft. lbs. to be sure all parts are properly seated.
5. Back off nut one flat (1/6 turn). If locking holes line up insert cotter pin. If not continue to back off nut to nearest locking hole. Final adjustment should be 1 to 1½ flats turn, backed off from initial tightened position. This should result in the desired limits of .001-.010″ end play.
6. Install cotter pin, dust cap and wheel.

Checking Curb Height

The suspension parts must be at normal curb height position when checking wheel alignment. This can be obtained by jouncing front and rear of car up and down, decreasing the amount of movement until parts reach normal curb height position.

To determine whether front and rear suspension height is normal, compare measurement on car with others of the same body type and having comparable equipment. Measurements should be taken as shown in Figs. 3 and 4.

The tendency to remain upward and downward will be more noticeable on new cars on which suspension joints have not yet become burnished and completely free. For this reason, checking of caster and camber on new cars should not be done unless the height is set to correspond with the height of the front end of a similar model that has freed up

Fig. 1 Front suspension. Note location of camber and caster adjusting shims

Fig. 2 Rear suspension. Note location of shims for rear wheel toe-in adjustment

after usage. Blocks or spacers made of rod or tubing will be useful in positioning parts.

Caster, Adjust

Caster adjustment is made by shimming front and rear on upper control arm. If sufficient adjustment cannot be obtained by shimming, it will be necessary to adjust the length of the strut rod. Lengthening this rod, Fig. 1, by turning the nut increases caster; shortening the rod by turning the nut decreases caster.

Proper strut rod adjustment is necessary to prevent misalignment of lower control arm and bushing in front crossmember. Proper caster adjustment with equal shims at upper arm is given in the *Wheel Alignment* chart.

After adjustment, tighten nut at rear of strut rod to 70-85 ft. lbs. and bend overlocking tab on two sides of nut. Be sure all strut nuts are tight before taking final adjustment reading.

Fig. 3 Measuring front suspension curb height. For 1962 measurement is 5 1/16" to 5 5/16"

Camber, Adjust

Camber adjustment is made by means of shims between upper control arm inner shaft and front crossmember, Fig. 1. Although shims can be changed at either the front or rear attachment, it is important that the shimming be done equally so as to have no effect on caster. Adding shims at both front and rear of support shaft bolts will decrease positive camber.

Loosen the upper shaft bolts and add or remove shims equally as required and tighten bolts. It may be necessary to remove the wheel to secure these bolts to a torque of 55-70 ft. lbs.

To compensate for drift to the right, induced by road surface camber, it is desirable that the left camber be set ¼° greater than the right camber.

Toe-In, Adjust

1. Remove horn button and set gear on high point of worm by turning steering wheel until mark on shaft is exactly at top. This mark locates center of gear travel or straight ahead position.
2. Loosen tie rod end clamp bolts and turn tie rod tubes an equal amount until toe-in is correct. Turn right tie rod in direction of forward rotation of wheels to increase toe-in; turn left tie rod in opposite direction to increase toe-in.
3. If straight ahead position of front wheels are not equal, turn both tie rod tubes in same direction (so as not to change toe-in) until both wheels are equally facing straight ahead. Re-check toe-in.
4. Tighten tie rod adjuster sleeve bolts to 14-20 ft. lbs., making sure bolts are to lower side of tie rod and at a 25° angle to vertical with head of bolts toward rear of car.

Rear Suspension Toe-In

If the rear wheels are notably tilted just after car has been lowered to floor, roll car back and forth a few feet to bring wheels back to normal position.

If drive on type equipment is used, reverse car and back it into position. *Toe-in (overall) will be read as toe-out when car is backwards, because readings will be taken from rear of tires rather than front.*

Since the wheels are adjusted by adding or removing shims at the front edge of the differential, Fig. 2, both wheels are adjusted at the same time. With the design of this suspension, it is impossible to adjust one wheel at a time as shims must be added or taken away equally from each side.

A shim added to each side will increase toe-in. Removal of a shim from each side will decrease toe-in. Shims must be added or removed in pairs. Toe-in is listed in the *Wheel Alignment* chart. After shimming is completed, loosen engine mount bolts, run engine to permit it to seek its natural position, and retighten bolts.

Due to manufacturing tolerance and parts stack up, it is possible to have toe-out on one wheel and toe-in on the other wheel. In this instance, adjust the suspension to bring the wheel with the toe-out as close to specifications as possible, but not letting the opposite wheel go out

Fig. 4 Measuring rear suspension curb height

of specifications. For example, if one wheel toes out by ¼" then opposite wheel must toe-in enough to give 0 to ⅛" overall toe-in.

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure the front wheel bearings are properly adjusted and that the control arms are tight. Then check ball joints as follows:

To check lower ball joint for wear, jack under the lower control arm (not under frame). Then grasp the tire at top and bottom and move it in and out. If movement at the edge of the tire exceeds ¼", the joint is worn and should be replaced.

To check upper ball joint, separate the joint from the steering knuckle. Then install and tighten the nut on the stud. The stud is then turned in its socket with a torque wrench. A torque range of ½ to 6 lb.-ft. is permissible.

FRONT END REPAIRS

Shock Absorber

1. Support vehicle at side rails so that suspension hangs free and that clearance is enough on lower control arms to allow removal of shock absorber, Fig. 5.
2. Unfasten shock absorber top and bottom and withdraw from below.
3. When installed, be sure that the upper grommet nut is bottomed at end of thread.

Coil Spring

1. Support vehicle at frame side rails to allow control arms to swing free and positioned so the arms may be raised or lowered with a hoist.
2. Remove shock absorber.
3. Remove two strut rods-to-control arm nuts. Place stand under lower control arm and take up slightly on spring compression.
4. Remove lower ball stud from knuckle. Carefully raise hoist until spring is free and withdraw spring. *A bar placed through control arm and into spring tower will retain spring and keep it from slipping until free.*
5. Reverse removal procedure to install spring, being sure rubber insulator is in place in crossmember spring tower.

Lower Arm and Ball Joint

1. To remove lower control arm, follow procedure for removing coil spring. Then remove control arm inner bolt and remove arm.
2. If ball joint is to be replaced, unscrew the ball joint (self-tapping) from control arm.
3. To install the new ball joint, screw it into the control arm. Install lube fitting and lubricate. Place rubber cap over stud.

Fig. 5 Front suspension components

Upper Arm and Ball Joint

1. Remove ball joint from knuckle.
2. Remove two nuts retaining upper control arm to crossmember, noting number of shims at each bolt.
3. Remove sheet metal access hole plugs opposite control arm retaining bolts and remove bolts through these holes.
4. To remove ball joint from control arm, drill through heads of rivets and cut off rivet heads with a chisel, being careful not to enlarge holes in control arm. Tap rivets out with a punch and remove from control arm.
5. Install new ball joint against top side of control arm. Secure joint to arm with four special alloy nuts and bolts furnished with replacement ball joint. Tighten nuts to 10-12 ft. lbs.
6. Install control arm, being sure to install same number of shims as removed at each bolt. Tighten nuts and bolts to 55-70 ft. lbs. Replace access hole plugs.
7. Install new rubber seal on ball joint stud and lubricate ball. Install ball joint through knuckle and tighten nut to 55-70 ft. lbs. Do not back off nut when aligning holes to install cotter pin.
8. When assembly is completed, bounce front end of vehicle to centralize bushings and tighten cross shaft nuts to 35-40 ft. lbs.
9. If ball joint was replaced or if proper number of shims were not reinstalled, recheck caster and camber.

REAR SUSPENSION REPAIRS

Shock Absorber

1. Place car on a "drive-on" (ramp) type hoist, frame contact hoist or

Fig. 6 Position of universal joint for rear spring removal

place jack stands under body at each side rail just forward of rear wheel openings. The body should be raised high enough so that wheels hang free and a floor jack can be placed under tire. Raise tire so that it is in its normal position. This will allow shock absorber to be removed without interfering with the floor.

2. Remove attaching bolts, upper and lower, and withdraw shock absorber.
3. To install, pull out shock absorber shaft to extend it to its full length.
4. Install shock absorber through lower control arm and spring. Install lower attaching spacers, lockwashers and tighten bolts to 15-25 ft. lbs.
5. Install upper bolt and lockwasher and tighten nut to 45-60 ft. lbs.

Coil Spring

1. Raise vehicle by body side rails so that control arms may swing free. Vehicle must be raised high enough so that a rolling floor jack may be placed under brake drum.
2. Loosen control arm cross shaft bolts (in ends of shaft). Disconnect brake hose from line at junction. Remove wheel and replace nuts on studs to hold drum in place.
3. Remove exhaust system.
4. Position U-Joint as shown in Fig. 6. *This must be done to allow axle shaft and control arm to swing down far enough to remove spring. It also will keep yoke on U-Joint from hitting axle case or side bearing adjustment nut.*
5. Place a rolling jack under drum and brake flange. Raise jack slightly to place a slight load on spring.
6. Remove shock absorber. Mark position of spring with relation to spring seat, Fig. 7, for reassembly.
7. Lower floor jack until spring can be pried out. *Do not remove or lower jack too far as this places too much strain on axle shaft. If both springs are removed, be sure to mark which side each spring goes on.*

Installation

1. Set spring into spring tower and pry into place in lower control arm. *Be sure that index marks line up.*
2. Extend shock absorber shaft and install, tightening lower bolt to 15-25 ft. lbs. Raise lower control arm and attach shock absorber at top, tightening bolt to 45-60 ft. lbs.
3. Connect brake line, remove floor jack and install wheel.
4. Lower vehicle to floor, jounce rear end of car several times and, with full weight on control arms, tighten cross shaft bolts to 45-55 ft. lbs.
5. Bleed and adjust brakes.

Lower Control Arm

1. Remove spring and shock absorber.
2. Before removing floor jack under drum, support control arm with jack stand.
3. Remove brake drum. Line up hole in axle shaft flange with backing plate nuts and remove nuts.
4. Pull backing plate outward slightly, then push it back onto control arm studs to loosen backing plate from bearing retainer.
5. Remove nuts from universal joint U-Bolts. Pull axle shaft out enough to separate yoke and remove U-Bolts.
6. Remove universal yoke and withdraw axle shaft.
7. Remove backing plate from control arm studs and tie backing plate up to crossmember with wire.
8. Unfasten control arm from crossmember.

Installation

1. Set control arm in place, install and tighten four nuts to 40-55 ft. lbs. *Be sure to attach parking brake bracket and tail pipe support to front two attaching bolts before installing nuts.*
2. Place jack stand under control arm.
3. Install backing plate onto control arm studs and temporarily install two nuts on studs.
4. Install axle shaft, yoke and U-Bolts. Remove two loose nuts from control arm studs and line up holes in axle bearing flange plate with control arm studs and push axle shaft inward until yoke is fully attached to U-Bolts. Install and tighten U-Bolt nuts to 14-20 ft. lbs. Tighten axle shaft flange nuts to 30-45 ft. lbs.
5. Install drum, making certain that holes in drum *do not* line up with hole in axle flange or dirt may get into brake assembly.
6. Install shock absorber and spring. Then bleed and adjust brakes.

Fig. 7 Marking spring and spring seat for reassembly

Fig. 8 Steering gear adjustments

HORN SOUNDER & STEERING WHEEL

1. Lift out horn button or ornament.
2. Remove two nuts and spacer from steering shaft.
3. Remove horn ring (Deluxe) or receiver cup.
4. Remove pivot ring (Deluxe) and bellville spring.
5. Remove contact assembly.
6. Use puller to remove wheel.
7. To replace, reverse removal operations, making sure wheel is in straight ahead position. Tighten wheel nut to 25-30 ft. lbs.

STEERING GEAR

Adjustments

There are two adjustments on the steering gear, Fig. 8. They are worm bearing preload and sector and ball nut backlash. It is important that adjustments be made in the sequence mentioned. Failure to do so will result in damage to steering gear.

Worm Bearing Preload

1. Disconnect steering linkage from pitman arm. Tighten pitman arm nut to 100-125 ft. lbs.
2. Loosen steering column bracket to make certain it is not sprung due to misalignment. If misaligned, shim at steering gear housing-to-frame bolts and tighten bracket.
3. Loosen side cover lock nut and back off adjusting screw a few turns.
4. With spring scale hooked to rim of steering wheel, measure pull required to keep wheel in motion when off high point, at least 30° off center. Pull required should be between ¼ and ¾ lb. (manual gear) or ¼ to ⅝ lb. (power assist). To correct, loosen worm adjuster lock

Fig. 9 Steering gear components

nut with brass drift and turn adjuster to bring adjustment within limits.

5. Retighten lock nut to 18-27 ft. lbs. and worm adjuster lock nut 70-100 ft. lbs. Recheck adjustment.

Sector and Ball Nut Backlash

1. When worm bearing preload has been adjusted, side cover adjusting screw should be turned clockwise until a pull of ⅞ to 1½ lbs (manual gear) or ¾ to 1 lb. (power assist) at steering wheel rim is required to turn wheel through high point.
2. Tighten side cover adjusting screw and worm bearing adjuster lock nuts and recheck adjustments.

Steering Gear, Replace

1. Remove steering wheel.
2. Unfasten gear from frame and remove gear and shaft from car.
3. Remove plastic collar and felt seal from column.
4. Reverse removal procedure to install gear and tighten attaching bolts to 70-90 ft. lbs.
5. On power steering cars, be sure to secure booster cylinder shaft bracket with two lower steering gear attaching bolts.

Steering Gear Repairs

1. Referring to Fig. 9, turn steering gear to center of travel and remove side cover adjusting screw lock nut. Remove side cover and gasket by turning adjusting screw clockwise through cover.

Fig. 10 Ball nut properly installed on shaft

Fig. 11 Adjusting worm bearing preload

Fig. 12 Power steering installation

Fig. 13 Power steering pump components

2. Remove adjusting screw from slot in end of pitman shaft. Make sure shim found on adjusting screw remains with screw.
3. Remove pitman shaft from housing.
4. Remove worm bearing adjuster lock nut and remove adjuster and lower bearing.
5. Push worm and shaft with ball nut through bottom of housing and remove upper bearing.
6. Remove ball nut from return guide clamp, remove guides. turn nut over and remove balls. Rotating shaft slowly from side to side will aid in removing balls.
7. Remove ball nut from worm. Unless all balls are removed nut cannot be removed.

Assemble

1. All seals, bushings and bearings should be lubricated before assembly.
2. Place ball nut on worm so deep side of teeth are located as shown in Fig. 10.
3. Install 20 balls in each circuit (one circuit at a time) of ball nut, rotating steering shaft slightly to aid in installing balls.
4. Insert 5 balls in each return guide using vaseline to hold balls in place. Install guide clamp and screw. *Be careful that rotation of shaft does not cause balls to enter crossover passage between circuits as this will cause improper operation of ball nut.*
5. Place upper bearing on shaft. Center ball nut on worm, then slide steering shaft, bearing and nut into housing.
6. Install worm adjuster in housing just tight enough to hold bearing races in place. Final adjustment will be made later.
7. Install pitman shaft adjuster screw and selective shim in pitman shaft slot. *Screw must be free to turn but have no more than .002" end play. If too tight or too loose, select new shim to give proper clearance. Shims are furnished in several thicknesses, ranging from .063" to .069".*
8. Install pitman shaft as shown in Fig. 11. Install side cover and gasket on adjusting screw, turning screw counterclockwise until it projects through cover 5/8" to 3/4".
9. Install cover screws and tighten to 25-35 ft. lbs. Tighten pitman shaft adjusting screw so that teeth engage but do not bind. Final adjustment will be made later.
10. Fill steering gear with proper lubricant and adjust as outlined previously.

Fig. 15 Booster cylinder components

POWER STEERING

The power steering system consists of a pulley driven vane type pump, an oil reservoir which is part of the pump assembly, a double-acting power booster cylinder, and a hydraulic control valve, Fig. 12.

Pump, Replace

1. Drain system by removing inlet hose.

Fig. 14 Hydraulic control valve components

Disconnect outlet hose and connector.

2. Loosen pump bracket bolt, remove drive belt and pump assembly from car.
3. Install in reverse order of removal. Fill reservoir with Hydra-Matic fluid and run engine at a fast idle speed for 30 seconds. Refill pump and bleed system by running engine and turning steering wheel through entire range of travel to expel air. Check oil level and for leaks throughout system. Fig. 13 illustrates pump components.

Control Valve

Fig. 14 illustrates the components of the hydraulic control valve assembly. Because this valve is adjustable, it must be adjusted after being assembled. *The following steps should be followed in balancing a control valve. The same procedure may be followed to correct a complaint of harder steering effort required in one direction than the other.*

1. Install valve in vehicle. Connect all hoses and fill pump reservoir with oil. Do not connect the cylinder rod to the frame bracket. If the vehicle is already in operation, it will be necessary to detach the cylinder rod from the frame bracket.
2. With all hoses attached and proper amount of oil added to the system, the engine should be started with the car on a hoist. One of the two following conditions will exist.
3. If the piston rod remains retracted, the adjusting nut should be advanced until the rod starts to move out. The nut should then be backed off until the rod starts to move in. Reposition the nut to exactly ½ the rotation required to change direction of shaft movement.
4. If the piston rod extends upon starting the pump, the adjusting nut should be retarded until the rod starts to move in. The nut should then be advanced until the rod starts to move out. Reposition the nut to exactly ½ the rotation required to change the direction of shaft movement. *Do not turn the nut back and forth more than is necessary to balance the valve.*
5. When valve is balanced, piston rod should be able to be moved in and out manually.
6. The engine should then be turned off and the cylinder rod connected to the frame bracket.
7. Check by starting the engine with car on a hoist. If front wheels do not turn in either direction from center, valve action is correct. Install dust cap on end of valve.

Booster Cylinder

If repairs are to be made to the booster cylinder, refer to Fig. 15 for proper location of components.

Instruments, Radio & Windshield Wiper

INSTRUMENT CLUSTER

1. To remove cluster, disconnect battery.
2. Remove two ¼″ nuts, and four screws at lower edge of cluster housing.
3. Remove two screws from lower steering column bezel.
4. Remove speedometer cable.
5. Pull cluster and housing out of panel opening to gain access to wiring.
6. Starting at top, remove bulbs and wiring.
7. Remove four screws retaining cluster to housing. When cluster is removed, all instruments will be accessible for servicing.

RADIO, REPLACE

1. Disconnect battery ground cable.
2. Loosen hex screws and remove knobs.
3. Remove retaining nuts and escutcheon.
4. Remove screw securing radio to instrument bracket.
5. Disconnect antenna and power leads from radio and remove radio. *On air conditioned cars the glove box and left hand evaporator support must be removed and radio removed through this opening.*

WINDSHIELD WIPER

1. To remove wiper motor, remove hoses and wire terminals connected to motor.
2. Remove clip securing wiper crank to transmission arm. This connects inside car at fire wall under instrument panel.
3. Remove attaching screws and remove wiper from fire wall.

②—Intake 29°, exhaust 44°.
③—Cast iron cylinder head.
④—Aluminum cylinder head.

ENGINE TIGHTENING SPECIFICATIONS★

★Torque specifications are for clean and lightly lubricated threads only. Dry or dirty threads produce increased friction which prevents accurate measurement of tightness.

①—Fit rings in tapered bores for clearance listed in tightest portion of ring travel.
②—Piston should support its own weight in cylinder with all parts clean and dry.

GENERATOR AND REGULATOR SPECIFICATIONS

★To Polarize Generator: For internally grounded systems, disconnect field lead from regulator and momentarily flash this lead to the regulator battery terminal. For externally grounded systems, reconnect the leads to the regulator; then momentarily connect a jumper wire from the "Gen" (Delco-Remy) or "Arm" (Auto-Lite) to the "Bat" terminals of the regulator.

Engine Section

ENGINE MARKINGS

Engines are stamped with a three-letter code which is stamped adjacent to the engine identification code number. The code is as follows:

First letter means size of bore.

Second letter means size of main bearings.

Third letter means size of rod bearings.

Letter "A" means standard size.
Letter "B" means .010″ undersize.
Letter "C" means .010″ oversize.

Engines not so marked are standard in all respects.

On six-cylinder engines a five digit engine code number is located on a machined surface on the upper left corner of the engine block. On V8 engines the engine code number is stamped on a tag attached to the generator mounting bracket.

V8 engine

ENGINE REPLACE

1961-62 Six

1. To remove, mark hood hinge location on hood panel to aid in reassembly before removing hood.
2. Drain cooling system and engine oil.
3. Remove starting motor and radiator.
4. Disconnect exhaust pipe from manifold.
5. Remove flywheel housing-to-engine screws.
6. Remove flywheel mud pan.
7. On automatic transmission cars, drain converter and transmission and remove six screws from flywheel drive plate-to-converter.
8. Remove front engine support upper nuts.
9. Disconnect all wiring, lines and hoses from engine, and power steering (if equipped).
10. On air conditioned cars, remove compressor and bracket (system need not be discharged).
11. Attach lifting rig to engine and lift out forward and upward to clear clutch shaft pilot bushing through hood opening.

1961-62 V8

1. Remove battery and hood.
2. Drain oil and cooling system. On automatic transmission cars, drain transmission and disconnect transmission cooler lines at radiator and straps on engine oil pan.
3. On air conditioned cars, unfasten and move compressor and hoses to one side.
4. Remove radiator and exhaust manifolds.
5. Disconnect all wiring, lines and tubes from engine.
6. Remove starting motor and flywheel housing mud pan.
7. On automatic transmission cars, drain converter and loosen flywheel drive plate from converter.
8. Attach lifting rig to engine.
9. After supporting transmission and torque tube, remove transmission crossmember.
10. Loosen front engine mounting cushions and remove engine from car.

Six cylinder overhead valve engine

Six cylinder side valve engine

1956-60 V8

1. To remove the engine separately from the transmission, drain cooling system and oil pan.
2. Remove hood, radiator, air cleaner, battery and starter.
3. Remove fuel lines, vacuum lines, accelerator linkage as necessary, hoses and wires attached to engine units.
4. On cars with Standard or Overdrive transmissions, remove the transmission.
5. On cars with Flash-O-Matic transmission, unfasten torque converter housing from flywheel housing.
6. Remove engine mounting bolts, and support automatic transmission with a jack.
7. Attach a lifting rig to the engine and raise it out of the chassis.

1955 Rambler and 1958-60 American

1. On these models the engine is removed from below the car. Remove hood and radiator and disconnect fuel lines, vacuum lines, accelerator linkage as necessary, hoses and wires attached to engine units.
2. Remove exhaust pipe from engine and wire it upward and clear of exhaust pipe mounting studs.
3. Attach lifting rig to cylinder head and raise car on a hoist (twin-post type preferably). If a lift is not available, support front of car with high jacks located under body side sills just behind the rear engine support crossmember.
4. Disconnect cross tie rod from steering linkage, shift rods from transmission and clutch linkage to clutch beam.
5. Drain engine and transmission oil.
6. Disconnect speedometer cable.
7. Attach block and tackle or crane to lifting fixture and adjust to support engine's weight.
8. Remove four bolts holding front support cross member to body side sills.
9. Remove rear engine mounting diagonal braces, and the four bolts which

V8 engine lubrication

Fig. 1 Cylinder head tightening. V8 engines

Fig. 2 Cylinder head tightening. Rambler side valve engine

Fig. 3 Cylinder head tightening. Rambler overhead valve engine

Fig. 4 Cylinder head tightening sequence. 1961-62 aluminum engine

attach the rear engine support cross member to the body side sills.

10. Lower engine slightly and a little forward and slip universal joint from transmission shaft.
11. The engine can be lowered to the floor with cross members attached.

1956-60 Six-Cyl. (Except American)

The general procedure for removing the engine is to raise or remove hood, drain cooling system and remove battery and radiator. Disconnect fuel pump, exhaust pipe at manifold, accelerator linkage, and wires attached to engine units. Remove engine support bolts and hoist engine out of chassis.

CYLINDER HEAD

V8 Engines

The cylinder head block surface has two locating dowels to assist in lining up and holding the position of the head and gasket during installation and removal.

After installing push rods, rocker arms and cylinder head cap screws, tighten the cap screws in the sequence shown in Fig. 1, and to the torque values given in the *Engine Tightening Chart.*

The cylinder head and rocker arm cap screws are of various lengths and design, among which are two special tapped heads to accommodate the retaining screws that hold the rocker arm cover; three long plain cap screws to retain rocker arms and cylinder head, and one special bolt to index with oil holes for rocker arm lubrication. *This special 6⅜" long drilled bolt is part of the lubrication system and must be installed in the rear position to index with oil passages in the tappet area.*

Six-Cylinder Engines

Tighten cylinder heads in the order shown in Figs. 2 and 3 and to the torque given in the *Engine Tightening Chart.* On overhead valve engines be sure to adjust the valves after the tightening operation.

Service Note, Aluminum Engine

When servicing the cylinder head on aluminum engines, note that the following bolts are used:

Quantity	Bolt Size
8	$5\frac{9}{16}$"
5	$4\frac{5}{16}$"
2 standard	5"
8 battery type	5"

It is possible to install the $5\frac{9}{16}$" bolts where the standard 5" bolt should be used; should this happen the longer bolt will bottom and the aluminum cylinder head will be damaged.

Tighten cylinder head in the sequence shown in Fig. 4. After engine has been warmed up to normal operating temperature, recheck torque.

VALVE ARRANGEMENT

Front to Rear

V8 Engines ..... E-I-I-E-E-I-I-E
6-Cylinder ..... I-E-E-I-I-E-E-I-I-E-E-I

VALVES ADUST

Mechanical Lifters

Overhead valve engines should always be adjusted whenever the cylinder head has been removed or tightened. The clearances given in the *Valve Specifications* chart should be maintained at all times for normal driving conditions. Check the clearance when the engine is at normal operating temperature and at idling speed.

ROCKER ARMS

To remove the rocker arms, take off rocker arm cover, unfasten rocker arm shafts, support bolts and oil fittings and lift off the assembly.

When disassembling, place all parts on the work bench in their proper relationship to insure correct assembly. And to prevent the possibility of bending or twisting push rods, they should always be removed before taking off the cylinder head, and replaced after the head is installed.

Fig. 5 Checking valve spring installed height

VALVES, REMOVE

Side Valve Engines

Drain the cooling system and remove cylinder head. Take off valve covers and plug openings in cylinder block around valve lifters so that the valve locks will not drop into the oil pan when the locks are removed. Compress the valve spring, remove the valve lock and lift out the valve.

Overhead Valve Engines

With the cylinder head removed, place a suitable holding strap over the valve heads to hold the valves in place while compressing the valve springs. In using the valve spring compressor, do not compress the springs any more than is required to remove the valve locks. If they are compressed to the point that the coils bottom, the spring may lose as much as 10 to 15 lbs. tension.

After removing all locks and springs, invert the head and lift out the valves. Place the valves in a board with numbered holes so they can be identified as to the valve port from which they were removed.

Fig. 6 Holding valve lifters up with rubber bands while removing camshaft on six-cylinder overhead valve engines

Fig. 7 Hydraulic valve lifters

On V8's the valve seals are mounted onto the valve guides. When servicing valves the valve stem oil seals should be replaced to insure good oil control at this point.

VALVE GUIDES

Valve guides are removed and replaced with special pullers and drivers made for the purpose. If this equipment is not available, carefully measure with a steel scale the amount each guide projects from the valve port before removing it so that the position of the new guide will be properly located when it is driven in. After the new guides are installed, they should be reamed to provide the clearance within the limits given in the *Valve Specifications* chart.

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 5. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16", and since the acceptable valve head margin is approximately $\frac{3}{64}$" to $\frac{5}{64}$", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

Wash all valve springs in a suitable solvent. Examine the springs for damage or corrosion due to acid etching which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture if one is available. If not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications given in the *Valve Specifications* table within 10% should be replaced. Likewise any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

Fig. 8 Valve timing for V8 engines

Fig. 9 Valve timing for Rambler and Nash 6-cyl. engines

VALVE LIFTERS

Mechanical Lifters

Since these lifters are of the mushroom type and the guides are cast integral with the cylinder block, it is necessary to remove the camshaft before the lifters can be taken out. Follow the instructions for removing the camshaft under that heading; then remove the oil pan and take the lifters out through the bottom.

To make removal of the camshaft easier, hold up the lifters with rubber bands on overhead valve engines, Fig. 6.

Hydraulic Lifters

The hydraulic valve lifters used are simple in design, readjustments are not necessary and servicing them requires that care and cleanliness be exercised in the handling of parts, Fig. 7.

The easiest method for locating a noisy valve lifter is by the use of a piece of garden hose approximately 4 feet in length. Place the end of the hose near the end of each intake and exhaust valve with the other end of the hose near the ear. In this manner, the sound is localezed, making it easy to determine which lifter is at fault.

Another method is to place a finger on the face of the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be removed and cleaned. If dirt, varnish, carbon, etc. is found to exist in one unit, it more than likely exists in all the units.

Plungers are not interchangeable as they are selectively fitted at the factory. Should a plunger or lifter body become damaged, it is necessary to replace the entire unit.

The plunger must be free in the lifter body. A simple test for this is to be sure the plunger will drop of its own weight in the body. There must be no excessive leakdown and there must be no ball check valve leakage.

When removed, valve lifters should be placed in a rack in their proper sequence

so they can be installed in the original locations in the block. To service lifters, proceed as follows:

1. Hold plunger down with push rod and, using a small screw driver or awl, remove plunger retainer, Fig. 7.
2. Remove parts from lifter body.
3. Clean all parts and inspect for damage. If any parts are damaged, the entire lifter assembly should be replaced.
4. When assembled, compress plunger to open oil holes and fill plunger with SAE 10 oil. Work plunger up and down and refill.

TIMING CHAIN COVER

When installing the cover it is important that the cover be properly aligned when installing the vibration damper to prevent damage to the oil seal. This is accomplished by leaving the cover-to-block cap screws loose until the vibration damper has been partially installed. Then tighten the cover screws.

TIMING CHAIN

When installing a timing chain, see that the timing marks on the sprockets are in line as shown in Figs. 8 and 9.

CAMSHAFT

To remove camshaft, remove all valve lifters on V8's, or prop them up as shown in Fig. 6 on six-cylinder engines. Take off timing chain and sprockets. Remove fuel pump, distributor and distributor-oil pump drive gear. When withdrawing camshaft from engine, use care to avoid damage to the camshaft bearings.

When installing the timing chain, be sure to align the timing marks as shown in Figs. 8 and 9.

PISTONS & RODS, REMOVE

After removing cylinder heads and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove connecting rod caps and push the pistons and rods out through the top of the cylinders, using care to prevent the big end of the rods from damaging the crankshaft or cylinder bores. Make sure the rods and pistons are properly numbered so they can be reinstalled in their original bores. It is advisable to install caps on rods as they are removed to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

V8 Engines

To insure proper installation of the piston in the bore, a notch is cast in the piston top and the letters "F" cast in the pin boss structure at the front, Fig. 11.

Fig. 11 Piston and rod assembly. V8 engines

Overhead Valve 6-Cyl.

Pistons are marked with a depression notch on the top perimeter, Fig. 12. When installed in the engine this notch must be toward the front of the engine. Always assemble rods and caps with the cylinder numbers facing the camshaft side of engine.

1955 Side Valve 6

When installed, the heavy or offset side of the rod must be placed opposite the camshaft side, and the identification marks on the rod must be toward the front of the engine.

1958-62 Side Valve 6

When installed, the identification knob on the connecting rod and the notch on the top of the piston must face front of the engine.

PISTONS

If the pistons are to be reused with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an old piston ring, filing the broken end to a sharp, square edge and using it to scrape the carbon. Soak the piston in solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material. Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Rinse the piston in solvent and wipe off the carbon on the sides of the piston. Never use a wire brush to clean a piston as the brush will round off the edges of the ring lands. Pistons showing scuffed or score marks on the skirt should be scrapped. Examine the ring lands carefully for cracks. If the piston is in the least bit doubtful, it should be discarded.

New pistons should be fitted according to recommendations given in the *Piston Specification* chart.

PISTON RINGS

When new piston rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled but without increasing the bore's diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with either end of the piston, then measure the gap with feeler gauges. If

necessary to increase the gap, file the ends of rings carefully with a smooth file.

PISTON PINS

V8's & OHV Six

Pins are a press fit in the connecting rod, thus requiring no locking device. The pin should be a palm press fit in the piston with parts at normal room temperature (70°F.). And with parts clean and dry, the pin must support its weight in a vertical position over its entire length in either of the two piston bosses.

1955 Side Valve 6's

The pin is locked in place in the rod by means of a lock bolt. To fit a pin, first hone the rod to fit the pin. Then hone the piston to allow a thumb press fit with the parts at normal room temperature.

1958-62 Side Valve 6's

The piston pins are a press fit into the connecting rod, thus requiring no locking device. The procedure for installing pins is the same as that given previously for 1956-61 overhead valve sixes.

1955 OHV Six

The pin is full-floating and held in position by lock rings in the piston bosses. To fit a pin, first hone the pin bushing in the rod to allow a thumb press fit with the parts at normal room temperature. Then hone the pin holes in the piston bosses to allow a palm push fit with the piston heated.

ROD BEARINGS

Service bearings are furnished in standard size and several undersizes, including undersizes for reground crankshafts.

The clearance for connecting rod (and main) bearings may be checked with Plastigage which is available at any auto parts jobber and full instructions for its use are furnished with the envelope in which it is contained.

Lacking Plastigage, however, clearance may be checked with a .002 in. test shim, ¾ in. square. Place the shim between the bearing and shaft journal. Install the bearing cap and tighten the nuts to the recommended torque. A locked bearing or drag when the rod is moved endwise on the crankshaft indicates the clearance is correct providing the rod moves endwise freely without the test shim installed. Do not overlook removing the test shim.

MAIN BEARINGS

Main bearings are the shell type and can be removed and replaced without removing the crankshaft. The bearings are made to size and do not require line reaming or readjustment.

When it is necessary to install new bearing shells, it is advisable to measure the shaft journals with a micrometer for being out-of-round. If an out-of-round condition exists in excess of the standard running clearance of the bearings

Fig. 12 Piston location reference notch. Rambler and Nash engines

(either main or connecting rod) a satisfactory bearing replacement cannot be made and it will be necessary to replace or regrind the crankshaft.

Use a rifle brush to clean the oil passages in both the shaft and crankcase. If possible, blow out the oil holes with compressed air. Be sure the journals are not nicked or scored and that all parts are thoroughly clean.

After installing the bearings, check the running clearance to be sure it is standard (see *Engine Bearing Data* chart). Use Plastigage or a .002 in. test shim about one inch square. Place the shim between the shaft and bearing and tighten the bearing cap nuts to the recommended torque. The shaft should be locked if the clearance is at the low limit or show a drag if at the high limit when turned, proving that the clearance is correct. Do not overlook removing the test shim.

CRANKSHAFT REAR OIL SEAL

V8 Engines

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding ends of the seal with a sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced it is possible to do the job without removing the crankshaft as follows:

To remove the seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜" from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is to be installed. Then exert a firm, steady pull on the wire or string and at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

1955 Ambassador Six

The threaded oil return has a steel-backed rubber seal. The seal is in halves and fits closely over the edge of the rear bearing oil return groove. It bears firmly on the smooth area of the crankshaft.

6-Cyl.

Oil sealing at the rear main bearing is similar to that used on V8 engines, and installation of the seal is accomplished in the same manner.

OIL PAN

V8 Engines

If the steering linkage hampers the oil pan's removal, disconnect it and allow it to settle away from the bottom of the engine. Then unfasten and remove the oil pan.

6-Cyl.

In order to remove the pan it will be necessary to remove the steering linkage cross tie rod. And on 1953-56 Statesman and Ambassador, the front suspension pivot bar brace will also have to be removed.

OIL PUMP

V8 Engines

Oil pump removal or replacement will not affect distributor timing as the distributor drive gear remains in mesh with the camshaft gear.

Upon disassembly of the oil pump, locate a straight edge across the pump body and gears in the body and check the gear-to-cover clearance, which should not exceed .004". A clearance of .008" maximum should exist between gears and walls of pump body.

The pump cover should be installed with the pump out of the engine and pump checked for freedom of operation before installation.

The oil pressure relief valve, which is built into the pump, is not adjustable, the correct pressure being built into the relief valve spring.

6-Cyl.

The oil pump on these models consist of a drive and driven gear. The drive shaft being keyed to the drive gear at the lower end, is driven by a gear at the upper end which engages with the camshaft gear. The distributor drive is taken from the top end of the oil pump drive shaft. A wire snap ring is used on the undercut on the lower end of the shaft

Fig. 16 Ignition details. V8 engines with Delco-Remy distributor

Fig. 15 Ignition details. V8 with Auto-Lite distributor

to prevent the shaft from disengaging the lower gear when the oil pump is removed.

RADIATOR, REPLACE

To remove, drain cooling system and disconnect hose. Unfasten radiator from its support and lift it out.

WATER PUMP

1. To remove the water pump, drain cooling system.
2. Remove fan belt, fan and pulley.
3. Unfasten and remove water pump from water manifold.
4. To disassemble, remove the bearing lock ring. Place pump in an arbor press and push hub, shaft and bearing out of impeller and cover. Then press shaft and bearing out of hub.
5. If the thrust seal surface in the housing has become rough, it should be refaced with a water pump facing tool. Use a new fan hub to insure a tight fit on the shaft. Insert the shaft in the housing and install the bearing lock ring. Then install a new seal assembly in the impeller and press the impeller on shaft so it is flush with end of shaft.
6. Install pump in reverse order of removal.

DISTRIBUTOR

1. Disconnect distributor primary wire from coil terminal.
2. Remove distributor cap and rotor. *Mark position of rotor arm on distributor housing so distributor can be installed in same position.*
3. Remove vacuum line from distributor.
4. Remove distributor hold-down clamp.
5. Note relative position of distributor in block, then work it out of the engine.

Installation

1. Turn rotor about ⅛ of a turn counterclockwise past the mark previously placed on the distributor housing.
2. Push the distributor down into the block with the housing in the normal "installed" position. *On gear-driven distributors, it may be necessary to move the rotor slightly to start gear into mesh with camshaft gear, but rotor should line up with mark when distributor is down in place.*
3. Tighten distributor clamp screw snugly and connect vacuum line, primary wire to coil, and install cap. If spark plug wires were removed from cap on V8's, refer to Figs. 15 and 16 for correct installation.

V8 Service Note

If the engine was disturbed while the distributor was removed from the engine, first crank the engine to bring No. 1 piston up on its compression stroke and continue cranking until the timing mark is adjacent to the timing indicator. Then rotate the distributor cam until the rotor is in position to fire No. 1 cylinder. Install the distributor as outlined above and set the ignition timing as directed below.

IGNITION TIMING

With the breaker points adjusted to the proper clearance, crank the engine to bring No. 1 piston up on its compression stroke and stop when the mark on the vibration damper lines up with the timing tab attached to the chain cover. Loosen the distributor clamp and rotate the distributor until the points just break. Tighten the distributor clamp.

When a timing light is used the engine should be run at hot idling speed for if it is turning faster the spark may be advanced by the centrifugal weights in the distributor and the timing will not be correct.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient

vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck either in the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Move the valve up and down a few times to work in the oil. *Never use engine oil for this purpose as it will leave a residue which hampers valve operation.*

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

CARTER NOTES

METERING ROD

AS—Metering rod should just bottom at wide open throttle. Adjust by bending metering rod arm.

WCD, WCFB and WCD—Metering rod adjustment must be made after the pump setting. Back out throttle lever set screw to seat throttle valves in carburetor bores. Loosen metering rod arm clamp screw. With metering rods in place, press down on vacumeter link until metering rods bottom in casting. Holding rods down, revolve metering rod arm until finger on arm contacts lip of vacumeter link. Hold in place and tighten clamp screw.

YF—With throttle valve seated in carburetor bore, press down on upper end of diaphragm shaft until diaphragm bottoms in vacuum chamber. Metering rod should contact bottom of metering rod well, and metering rod arm should contact lifter link between springs and at supporting lug. Adjust by bending lip up or down.

CARTER NOTES
continued

Fig. ①—WCD float level. To adjust bend float lever.

Fig. ②—With throttle valves closed and pump connector link in outer hole of pump arm, flat on pump should be parallel with a straightedge placed across dust cover boss. Adjust by bending throttle connector rod.

Fig. ③—With choke valve closed, tighten fast idle screw on high step of fast idle cam until there is the clearance specified between throttle valve and carburetor bore.

Fig. ⑦—With throttle valve wide open there should be the clearance specified between lower edge of choke valve and inner wall of air horn. Adjust by bending arm of choke trip lever.

Fig. ④—With throttle wide open there should be the clearance specified between upper edge of choke valve and inner wall of air horn. Adjust by bending ear on throttle shaft lever.

Fig. ⑤—YF and YH float level. Adjust by bending float lever.

⑥—With choke valve closed and fast idle cam in fast idle position, there should be the clearance specified between throttle valve and carburetor bore (side opposite idle port). Adjust by bending choke connector link.

Fig. ⑧—AS float level. Adjust by bending float lip.

Fig. ⑨—Pump arm on lifter link should parallel top of casting. Adjust by bending pump arm.

Fig. ①—Measured from roof of float chamber to lowest point of float with carburetor inverted.

HOLLEY NOTES

③—With throttle lever in wide open position and choke plate closed against unloader lever, opening of choke plate should be as specified between edge of choke plate and venturi. Adjust by bending unloader lever.

④—With carburetor inverted, adjust float level by means of adjusting nut on fuel bowl so float is parallel with bowl floor.

⑤—With engine idling, turn adjusting nut on fuel bowl until fuel just dribbles out of sight plug hole.

⑥—With engine idling, turn fast idle screw against high step of fast idle cam.

⑦—With engine idling, there should be the clearance specified between bowl vent valve and machined surface of bowl. Adjust by bending vent valve operating rod.

⑧—With throttle plates fully open and pump lever in compressed position, turn override spring screw until it just touches pump lever; then tighten screw 1/4 turn.

Fig. ②—Measured with scale through power valve mounting hole from outside surface of main body to level of fuel. Take measurement with engine idling.

⑨—With throttle plates wide open, clearance between top edge of choke plate and inner wall of air horn should be as specified. Adjust by bending tab on throttle shaft lever where it contacts fast idle cam.

Fig. ⑩—Primary float 7/8", secondary 11/16". Adjust by bending tab on float lever.

⑪—With engine idling, fuel should just dribble out of sight plug hole. If not, adjust float level.

⑫—See Fig. ⑩. Primary float 13/16", secondary 3/4".

⑬—With engine idling, turn fast idle screw so that it just touches lowest step on fast idle cam.

⑭—Use Gauge J-10231.

Clutch and Transmission Section

CLUTCH PEDAL, ADJUST

1955-62

In order to provide sufficient free movement of the clutch release bearing when the clutch is engaged and pedal fully released, free pedal play should be ½ to ¾″ at all times.

Adjustment for free pedal play is made by varying the length of the beam or link to the release lever rod. Lengthening this rod reduces pedal travel; shortening it increases pedal play.

CLUTCH REPAIRS

Removal

Remove the floor board. Disconnect the release fork pull-back spring and remove the clevis pin from the end of the release fork rod. Disconnect the release fork at the pivot and pull the fork out as far as possible. Remove the transmission as described under *Transmission, Remove & Replace.*

Remove the clutch housing pan and mark the clutch cover and flywheel so that the clutch may be installed in the same relative position. Loosen the clutch cover bolts gradually and evenly until the clutch spring pressure is entirely relieved. Remove the bolts, and the clutch assembly may be removed from below.

Service Note

Unless special clutch rebuilding equipment is available, it is recommended that the clutch assembly be exchanged for a rebuilt unit should the clutch require rebuilding. The driven disc, however, may be replaced without special equipment. If clutch rebuilding equipment is available, follow the equipment manufacturer's instructions, Fig. 1.

Clutch, Install

1. Very sparingly apply front wheel bearing lubricant to the clutch shaft pilot bearing in the crankshaft. If too much lubricant is used, it will run out of face of flywheel when hot and ruin driven plate facings. Make certain that flywheel surface is clean and dry.
2. Make sure that splines in driven plate hub are clean, and apply a light coating of lubriplate. Driven plate facings must be clean and dry.
3. Place driven plate on pressure plate, then place clutch assembly in position on flywheel, being sure to align marks made on flywheel and cover before removal.
4. Install cover bolts with washers but do not tighten.
5. Insert a spare clutch shaft through hub of driven plate and into pilot bearing.
6. Tighten each clutch cover bolt several turns at a time to draw cover evenly to flywheel and avoid distortion of cover.
7. While tightening cover bolts, move clutch shaft from side to side to center driven plate with pilot bearing. If driven plate is not centered, it will be difficult to slide the transmission into place. Make sure all cover bolts are uniformly tightened.
8. Remove aligning clutch shaft and install transmission, clutch linkage and adjust clutch pedal free play.

Fig. 1 Sectional view of Borg and Beck clutch

TRANSMISSION, REPLACE

1955-62 Except American

1. To remove the transmission, disconnect the brake tube bracket from the underside of the body floor pan.
2. Disconnect torque tube from rear of transmission.
3. On 1956-59, disconnect hand brake cable at bell crank and brake cable housing at bell crank bracket. On 1960-62, disconnect parking brake cable at equalizer and brake cable housing at torque tube bracket.
4. Move rear axle to the rear to permit the front universal joint to be taken off the transmission mainshaft.
5. Disconnect speedometer cable and shifter rods from transmission.
6. If equipped with overdrive, disconnect wires at solenoid and overdrive control cable at the lever on the overdrive housing.
7. Remove the two upper bolts from the transmission and insert guide pins in their place. Remove the two lower bolts and slide the transmission straight back on the guide pins until it is clear of the clutch disc.
8. To install, reverse the foregoing procedure.

1961-62 American

1. To remove transmission, disconnect rear spring front eye brackets from underside of body floor pan, rear shock absorbers at axle tubes, rear brake hose bracket, and hand brake cable at equalizer.
2. Slide rear axle to rear to remove front universal joint from transmission mainshaft.
3. Remove two top transmission mounting cap screws and insert guide studs in their place. Then slide transmission back and out to clear clutch pilot bearing and clutch disc.

1955 & 1958-60 American

To remove the transmission on 100″ wheelbase models, disconnect rear spring front eye brackets from the underside of the body floor pan, rear shock absorbers at axle tube, rear brake hose bracket, and hand brake cable at equalizer. Then slide rear axle to the rear to remove the front universal joint from the transmission mainshaft.

To remove the transmission on 108″ wheelbase models, remove the propeller shaft coupling nut from the coupling. Tap the coupling off the pinion shaft splines with a soft-faced hammer. Disconnect the crossmember from the support brackets at the side sills. Then remove the crossmember and both front and rear propeller shafts by sliding them from the transmission mainshaft.

On all models, after removing the two top bolts holding the transmission to the bell housing, install guide studs in these holes to avoid any possibility of damaging the clutch shaft or pilot bearing while removing the transmission.

TRANSMISSION REPAIRS

Type With Top Cover

1. Take off cover and gasket, Fig. 2.
2. Pull off companion flange.
3. Remove mainshaft rear bearing retainer and speedometer drive gear from mainshaft.
4. Remove main drive gear bearing retainer.
5. Remove small snap ring from main drive gear.
6. With brass drift and hammer, move countershaft rearward just enough to free up lock plate in shaft groove at rear end.
7. Make a dummy countershaft of ¾″ diameter cold rolled steel *exactly* $7\frac{5}{64}$″ long with a $\frac{3}{16}$″ hole drilled 1″

Fig. 2 Manual shift transmission with removable top cover

deep at each end. The purpose of the dummy shaft is to retain in position the needle rollers, sleeve and thrust washers when removing and installing the countershaft gear cluster.

8. Place the end of the dummy shaft against the front end of the countershaft and with a soft hammer, carefully drive the countershaft rearward out of the case, leaving the cluster gear, dummy shaft and related parts in the bottom of the case.
9. With a small brush, paint a fine line across the synchronizer rings, sleeve and second and high mainshaft gear to insure replacement of these parts in their original position.
10. To remove the main drive gear, place a brass bar or drift against the rear face of the drive gear teeth at the top (not synchronizer gear teeth) and carefully drive the gear and bearing forward out of the case.
11. With a brass bar placed against the front end of the mainshaft, drive the mainshaft rear bearing out through the rear of the case.
12. Using snap ring pliers, remove the snap ring from the front end of the mainshaft.
13. Holding the synchronizer parts and mainshaft gears together as a unit, move the mainshaft to the right and disengage the shifter fork and shoe from the grooves in the shifter sleeve and low gear. Then twist and withdraw the mainshaft through rear of case.
14. With a long brass drift, drive the reverse idler gear shaft out of the rear of the case and lift out the idler gear.
15. Lift the countershaft gear cluster and related parts straight out of the case to prevent the needle rollers from spilling. Then carefully remove the thrust washers and note the position of each to insure exact replacement.
16. With a punch, drive out the taper pins securing the shift shafts in position, upward out of the case.
17. Remove the nuts, washers and levers from the shift shafts and take shafts out of case. Also remove the interlock sleeve, detent balls, spring and pin.

Assembly Details — Regardless of appearance, all gaskets and oil seals should be replaced. When installing oil seals, coat the outside of the seal and inside of housing with red or white lead or gasket sealer to insure leak-tight joints. Leather seals should be soaked for 24 hours before installing them.

After installing the shift shaft levers, move either one into any in-gear position and with one end of the interlock con-

Fig. 3 Manual shift transmission with removable side cover

tacting a shift shaft cam, measure the clearance with a feeler gauge between the opposite end of the sleeve and the cam of the other shift shaft. This clearance should be .001″ to .007″. If not within these limits, remove the sleeve and replace with one of the proper length, available in five different lengths.

When installing the countershaft cluster gear, install the front washer with bronze face to the gear and lug at top. The rear inner (bronze) washer should be installed so the lugs will engage the slots in the cluster gear and the outer (steel) washer with the lug at top. With the countershaft installed temporarily, check the end play of the cluster gear. Do this by inserting a feeler gauge between the rear thrust washers. End play should range from .003″ to .006″. If greater than this, install new thrust washers.

With correct end play established, remove the countershaft with the dummy shaft, allowing the cluster gear and related parts to lie in the bottom of the case until after the main drive gear, mainshaft and reverse idler gears are installed. Then raise the cluster gear and install the countershaft.

Type With Side Cover

1. Referring to Fig. 3, remove overdrive assembly as outlined in the *Overdrive Chapter.*
2. Remove transmission cover.
3. Remove clutch shaft bearing.
4. Pull clutch shaft as far forward as possible.
5. Grasp mainshaft and its components and separate mainshaft from clutch shaft.
6. Slide mainshaft assembly out through rear of case.
7. Strip mainshaft of its parts.
8. Remove clutch shaft from rear of transmission.
9. The countershaft and reverse idler gear shaft are a press fit in the case and are locked in position at the rear by Woodruff keys. To maintain the position of the 80 needle bearings in the countershaft gear, drive the countershaft out of the rear of the case, using a dummy shaft machined to .870″ x $8\frac{1}{16}$″.
10. With countershaft removed, lift countergear assembly out through rear of case.
11. Knock out reverse idler shaft through rear of case.

Assembly Notes

Whenever any transmission gear requires replacement, the gear with which it meshes should also be replaced. To assemble the transmission, reverse the order of disassembly, referring to Fig. 3, and observe the following:

1. Use the dummy shaft to assemble the needle bearings in the countershaft. When assembling the thrust washers, the two small projections on the face of the bronze rear thrust washer must index with the grooves in the countershaft gear. The front thrust washer must index with the transmission case. Position the large thrust washer and place the assembly in the bottom of the case.
2. Install the reverse idler and shaft. Then align the countershaft gear assembly but before installing the shaft, check the washers for proper alignment.
3. To assemble the mainshaft, install mainshaft snap ring. This ring is furnished in four different sizes ranging from .087″ to .096″. Select the thickest snap ring that will fit into the retaining groove. Proper snap ring selection will reduce end play to a minimum.
4. Place oil baffle in overdrive adapter case with concave side facing forward.
5. Tap mainshaft and center bearing into housing.
6. Install large snap ring into retaining groove of adapter housing. Select the thickest snap ring (four sizes available) which will fit into groove.
7. Install sliding gear on mainshaft with shifting collar to front.
8. Install second speed gear on shaft

with tapered cone to front.
9. Install synchronizer on shaft.
10. Install lock ring and spacer on mainshaft.
11. Insert 14 pilot bearing rollers in rear of clutch shaft.
12. Insert clutch shaft in transmission from rear.
13. Insert mainshaft assembly through rear of case. Place clutch shaft on mainshaft. Place both shafts into proper position in case.
14. Check synchronizer friction rings for proper location and freeness.

Service Note

An excessive amount of grease used to retain the needle bearings in the clutch shaft when assembling a standard or overdrive transmission may lead to a failure. This results from insufficient lubrication when the grease plugs the three oil holes in the shaft and shuts off the oil supply.

A light coating of petroleum jelly or oil on the rollers will hold them in place until all are installed. Once installed, they will remain in place.

GEARSHIFT, ADJUST

Synchromesh Trans.

To adjust the gearshift linkage, place the shift lever in neutral. Disconnect the rods from the shift levers on the transmission and place the transmission levers in neutral position. Install an aligning tool (or a $\frac{3}{16}$" rod) in the small holes in the gearshift operating levers and the grooves in the bearing housing on the lower end of the steering column.

With the aligning tool in position and transmission shift levers in neutral, adjust shift rods at transmission end. After adjustment, remove aligning tool.

On 1960-61 models (except American) the shift gate must be pried downward to align the lever pins. This will lock both lever pins in the slot of the shift gate. Then move the operating levers down to the neutral position and adjust the trunnions on the gear shift rods so they will enter freely into the transmission shift levers while the shift levers are in neutral position.

HYDRA-MATIC

1955-57 Linkage, Adjust

1. Place selector lever in D-3 position.
2. Disconnect control rod at transmission lever.
3. Place transmission shift lever in D-3 position (3rd detent from front).
4. Adjust clevis so its pin passes freely through hole in shift lever.
5. After adjustment is made, lengthen control rod by turning clevis two full turns and connect clevis to shift lever.
6. To adjust gearshift selector pointer on Ambassador and Statesmen, remove Phillips screw from lower end of shroud on steering gear jacket tube. Pointer can then be moved on shaft by holding shaft with pliers and turning pointer by hand. Pointer is press fit on shaft.
7. The pointer on the 1955 Rambler is located on the selector shift lever. Adjustment is made by setting the lever in D-3 position and loosening the retaining screw and setting the pointer to correspond with the numeral 3. The pointer on the 1956-57 Rambler is a press fit on a split shaft and may be moved to any position.

Hydra-Matic, Replace

The Hydra-Matic transmission, rear flywheel housing, torus cover and torus members are removed as an assembly. The procedure is as follows:

1. Raise and support rear of car at body side sills. Support rear axle assembly with hydraulic jack.
2. Drain fluid from transmission.
3. Disconnect hand brake cable at bell crank and brake cable housing at bell crank bracket.
4. Disconnect speedometer cable and housing at transmission adapter.
5. Disconnect throttle rod from lever at transmission.
6. Disconnect control rod from transmission shift lever.
7. Remove rear brake hose bracket from floor pan to prevent damage to hose.
8. Disconnect torque tube from rear bearing retainer and separate by sliding the universal joint to the rear off the splines of the output shaft.
9. Support rear end of engine to relieve weight from rear engine support cross member.
10. Remove rear engine support cross member, cushion and bracket.
11. Remove flywheel housing lower cover.
12. Drain fluid from torus cover.
13. Remove throttle control lever from transmission to prevent bending it while removing and replacing transmission.
14. Remove 30 torus cover-to-flywheel attaching bolts.
15. Lower engine *slightly* to remove flywheel housing attaching bolts.
16. Place hydraulic jack under transmission and lift transmission slightly to take strain off rear flywheel housing bolts.
17. Remove rear housing-to-front housing attaching bolts. The lower studs on each side of rear housing also hold rear engine supports in housing.
18. Remove the upper rear stud on each side of housing and enter two $\frac{9}{16}$" studs approximately 2 inches long into the rear flywheel housing (one on each side) just above the dowel pins. Thread the bolts into the housing to force the dowel pins from the front flywheel housing. After dowel pins are free, remove the two studs.
19. Move the transmission to the rear of the car and lower the assembly after the mainshaft has been withdrawn from the crankshaft pilot bushing. To prevent end of mainshaft from striking the flywheel-to-crankshaft bolts when lowering the transmission, turn the flywheel so the end of the mainshaft will pass between the two bolts.
20. Reverse the foregoing procedure to install the transmission and adjust the linkage as previously outlined.

FLASHOMATIC TRANSMISSION

1959-61 Push Buttons

To adjust the gear selector push button control, disconnect the cable at the transmission lever. Push the "L" button in and move the selector lever at the transmission all the way to the rear which is low gear.

Adjust the cable linkage clevis, aligning holes in clevis and lever. Install clevis pin and washer and tighten clevis securely. Check adjustment in all positions.

1958 Push Buttons

To adjust the gear selector push button control, disconnect the cable at the transmission lever. Push the "N" button in and move selector lever on transmission all the way forward. Then set lever into first notch which is Neutral.

Adjust cable linkage clevis, aligning holes in clevis and lever. Install clevis pin and washer and tighten to clevis securely. Check adjustment in all five positions on the shift quadrant.

Selector Lever Linkage All 1957 & 1958-61 American

1. To adjust the linkage, set the selector in Reverse.
2. Disconnect clevis or trunnion at transmission lever and set transmission lever in Reverse position.
3. Adjust clevis or trunnion to transmission lever so that the pin passes freely through hole in lever.
4. Check selector lever pointer in all positions. If pointer does not line up properly, remove bottom half of jacket tube and adjust pointer to line up with center of letter N.

Transmission Removal 1957-61 Rambler

1. Disconnect battery cable.
2. Drain transmission.
3. Disconnect vacuum line and wire terminal at vacuum unit at rear of transmission.
4. Disconnect speedometer cable.
5. Disconnect rear brake hose bracket from floor panel.
6. Disconnect linkage from transmission lever.
7. Disconnect rear shock absorbers from rear axle.
8. Disconnect torque tube, propeller shaft and hand brake cable.
9. Lower rear axle and move rearward to separate torque tube and propeller shaft from transmission.
10. Support transmission with suitable hoist or jack.
11. Remove transmission-to-converter housing upper cap screws and install two guide pins in the cap screw holes.
12. Remove lower cap screws.
13. Remove transmission from converter assembly.
14. Reverse the foregoing procedure to install the transmission and adjust the shift linkage as outlined above.

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

REAR AXLE, REPLACE

1955 Rambler & 1958-61 American

1. Disconnect rear shocks at axle tubes.
2. Disconnect rear brake hose bracket.
3. Disconnect hand brake cable at equalizer.
4. Disconnect rear spring front eye brackets from underside of body floor pan.
5. Loosen coupling nut and remove propeller shaft. The coupling nut dust shield will serve as a puller to partially remove the propeller shaft from the rear axle pinion.
6. Separate axle from springs and slide axle back and out from under car.

1956-61 Except American

1. Raise and support rear of body.
2. Disconnect and remove hand brake cables from brake assemblies.
3. Disconnect torque tube from transmission.
4. Disconnect rear brake hoe at bracket on body floor pan.
5. Disconnect rear shock absorbers from mounting bracket, and the rear stabilizer bar at the axle tube.
6. Roll axle free from car and disconnect truss rods, torque tube and the propeller shaft from the rear axle. A slip type coupling is used between the propeller shaft and rear axle.
7. Reverse the foregoing procedure to install the axle.

REAR AXLE REPAIRS

1955-61

Fig. 1. In this type axle, the drive pinion is held in position by the shoulders in the differential carrier upon which the pinion bearing cups seat. The pinion position is maintained by a washer located between the rear bearing and the rear shoulder in the differential carrier. Shims between the bearing spacer and the front bearing cone are used to adjust pinion bearings.

The shimmed type of differential bearing adjustment is employed. The procedure for making this adjustment, as well as the assembly of the differential case, replacing the ring gear, checking ring gear and pinion backlash, and other differential case operations, is given in the *Rear Axle* chapter.

The axle tubes are pressed into the differential carrier to form a one-piece housing. To overhaul the unit, therefore, the axle assembly must be removed from the chassis.

Pinion, Replace

After removing the axle shafts and differential unit, take off the oil seal retainer and pinion retaining nut. The pinion may then be removed from the carrier by driving it out of the front bearing with a brass drift and hammer. After the pinion is free of the front bearing, pull it out through the rear of the carrier.

Mount the pinion in a press and force the rear bearing cone from the shaft. When replacing the cone, select a suitable sleeve or length of pipe of the same diameter as the cone so the rollers or cage will not be damaged when being pressed on the shaft. Drive the front bearing cup out of the carrier toward the front. If the rear bearing cup is to be replaced, remove it also.

Pinion Bearings, Adjust

The only occasion for adjusting the drive pinion bearings is when a new pinion or differential carrier is installed. To make the adjustment, install sufficient shims between the bearing spacer and the front bearing so that when the pinion retaining nut is tightened, all rollers in the bearings are tight, but still permit rotating the pinion by hand.

Pinion, Adjust

After adjusting the pinion bearings, the position of the pinion should be checked. If a pinion setting gauge is available, check the pinion depth as outlined in the *Rear Axle Chapter*. If a correction is necessary, disassemble the pinion and, if the pinion is to be moved toward the center of the axle, install a thicker washer. If the pinion has to be moved away from the center of the axle, install a thinner washer.

If no pinion setting gauge is available, assemble the differential unit in the carrier and check the tooth contact by painting the ring gear teeth as described in the *Rear Axle Chapter*. After satisfactory tooth contact has been established, lock the adjustment with the pinion shaft nut.

Fig. 1 Rear axle. 1955-61

AXLE SHAFTS

Removal, 1955-56 & Early 1957 Six

The rear wheel hub and drum are a one piece unit. The axle shaft is removed as follows:

1. Remove the wheel and use a puller to take off the hub and drum.
2. Block the brake pedal so it cannot

be depressed and disconnect the brake line from the wheel cylinder.
3. Remove the nuts and take off the outer oil seal, shims and brake support.
4. Pull out the axle shaft and bearing and inner oil seal with a suitable puller.

1957 Six (Late) & 1958-61

The hub and drum are separate units. The drum is attached to the hub by cap screws on V8s and by speed nuts on sixes. Also, the hub and axle shaft are serrated to mate and fit together on the taper. Both are punch marked to insure correct assembly, Fig. 3A. The axle shaft is removed as follows:

1. Remove the wheel and then remove the brake drum which is retained by cap screws on V8s and speed clips on Sixes.
2. Remove the hub with a suitable puller. *Do not use a knock-out type puller as damage to the wheel bearings or thrust block may result.*
3. Remove brake support plate, oil seal and shims.
4. Remove axle shaft with a puller

Service Note

Do not use an original hub on a replacement axle shaft; use a new hub. A new hub may be installed on an original axle shaft providing the serrations on the shaft are not worn or damaged. Be certain that the hub and axle shaft are punch marked to insure proper alignment on installation. A replacement hub, which is not serrated, can be installed and serrations will be cut in the hub when installed on the shaft due to the difference in hardness of the shaft and the hub.

When installing the hub onto the axle shaft tighten the axle nut to 150-200 lbs. ft. A measurement of $\frac{3}{16}$" should exist between the face of the hub and the outer taper of the axle shaft, Fig. 3A.

Fig. 3A Installing hub on axle shaft

Assembly

Replace the parts in the reverse order of their removal. If the old parts are replaced and the shims have not been disturbed, the axle shaft end play should be correct when the parts are assembled. However, if a new shaft, bearing, differential carrier or housing has been installed, it will be necessary to check the end play.

The end play can be checked when all parts have been replaced except the wheel and hub. To make this check, rap each axle shaft after the nuts are tight to be sure the bearing cups are seated. Then place a dial indicator so that its stem contacts the end of the shaft and work the shaft in and out to determine the amount of existing end play. If an adjustment is necessary, remove the outer oil seal and brake support and add or remove shims as required. When making this adjustment, an equal thickness of shims should be removed or added on each side of the axle housing to maintain a central position of the differential thrust block.

Service Note

The application of a bead of sealing material such as "Pliobond" or "Permatex" to the outer diameter of axle tube flange and the brake support contact area is recommended. Late production 1960 and 1961 models have a gasket installed at this location. On these models the sealing material will be used in addition to the gasket for improved sealing.

BRAKE MASTER CYLINDER, REPLACE

To remove the master cylinder, unhook the brake pedal return spring. Disconnect the master cylinder push rod from the brake pedal. Disconnect the brake lines from the connections on the master cylinder. Unfasten the cylinder from its mounting and remove from the car.

Install in the reverse order of removal and bleed the brake system.

Front End and Steering Section

CASTER & CAMBER

1955 Rambler & 1958-62 American

Fig. 1. To adjust caster, loosen the nuts at the inner end of the lower control arm pivot bar mounting screws and insert additional spacer shims at either point "A" or "B" as required. Adding shims at "A" increases caster and adding them at "B" decreases caster.

To increase camber angle, add an equal number of shims at both points "A" and "B". To decrease camber, remove an equal number of shims.

1956-61 Rambler

To adjust caster on these models, loosen the lower control arm attaching bolt nut. This will permit turning the bolt and eccentric to provide the necessary adjustment.

Fig. 1 Showing caster and camber adjusting shims at the lower control arm pivot bar mounting. 1955 Rambler and 1958-62 American

Service Note

The direction the eccentric is turned depends upon the position of the high spot on the eccentric. The procedure is to turn the eccentric in either direction until the desired movement takes place. If you continue turning past the high spot the movement will start to reverse. In other words, the high spot on the eccentric is the limit of adjustment in either direction.

TOE-IN, ADJUST

To adjust toe-in, loosen the clamps at both ends of the adjustable tubes on each tie rod. Turn the tubes an equal amount until the toe-in is correct. Turning the right tube in the direction the wheels revolve when the car is going forward increases the toe-in and turning the left tube in the opposite direction increases toe-in. To decrease toe-in turn the right

Fig. 2 1955-61 and 1962 American front suspension. Coil springs (not shown) act directly at steering knuckle supports. Control arms serve only for alignment purposes. Front suspension cross member is eliminated—suspension units are connected directly to body structure.

tube backward and the left tube forward. It is important that both tubes be turned an equal amount in order to maintain the correct position of the steering wheel. When adjustment is complete, tighten all clamp bolts.

Service Note

If a shimmy occurs at low speeds on a 1957 Series 10 or 30 or on a 1958 Series 20 or 80, a Teflon type thrust bearing kit is available for correction. The shimmy may result from chuck-hole contact or on driving over a rough railroad crossing. The parts in the kit replace the original upper control arm trunnion thrust ball bearing assembly. The Teflon bearing should be coated with a light film of chassis lubricant before installing it between the two races.

Check wheel balance and alignment and correct any excessive looseness in the steering gear and front suspension parts when the kit is installed.

Service Note

In performing service operations on the steering linkage or when adjusting toe-in, be sure to square the tie rod ball sockets on the studs and align the tie rod stud in the center, or slightly above center, of the cross tube opening, before tightening the steering linkage adjusting tube. This will prevent the stud from contacting the side of the cross tube opening, which would otherwise result in noise problems or damage.

Fig. 3 Removing front spring with special spring compressor. 1955-56

FRONT END REPAIRS

1955-61 & 1962 American

In contrast to the conventional type knee action, this design, Fig. 2, has the springs located above the upper control arms and can be removed and replaced with the use of a special spring compressor. To do this, support the front end of the car with a stationary jack under the frame and place an adjustable jack under the suspension unit. Take off the wheel and lower the suspension so the spring is distended. Then install the special spring compressor on the coils of the spring Fig. 3, and compress the spring by means of the turnbuckle. When sufficiently compressed, lift the spring from its lower seat and take it out of its upper seat.

On Rambler models, the upper and lower control arms are interchangeable from right to left suspension units. However, the front and rear horizontal arms have been provided with a two-degree twist at the inner ends and are identified with a stamping "R" and "L". Therefore, when assembling either an upper or lower control arm, the front and rear horizontal arms must be installed in pairs, one stamped "R" and one stamped "L".

On all models except Rambler, only the upper control arms are interchangeable between sides.

Fig. 4 is a layout of the steering knuckle assembly. Prior to installing the knuckle pin into the upper control arm trunnion, the spring seat must be bolted to the trunnion. Then install the knuckle pin, turn it up tight, and loosen it one complete turn. This will prevent the end of the pin bottoming when the front wheels are turned.

When installing a steering knuckle pin into a lower control arm trunnion, a clearance of approximately ¼ in. must be provided between the upper edge of the seal seat and the trunnion.

HORN SOUNDER & STEERING WHEEL

On models without horn ring, the horn button may be removed by twisting it out of the steering wheel hub. On models with horn ring, pry out the horn button and remove the horn ring.

After removing the steering wheel nut, use a puller to remove the steering wheel.

STEERING GEAR, REPLACE

1955-57 Rambler & 1958-62 American

Pull off the steering wheel. Disconnect the pitman arm from the steering gear and the tie rod from the steering arm.

On 1955 and 1958-62 American, after raising front of car, drain the radiator and remove the radiator-to-water pump tube.

On 1956-57 models, support the engine at the front and remove front engine support crossmember.

Remove steering gear to body sill mounting bolts and remove the steering gear from the bottom without removing the jacket tube.

1958-62 (Except American)

The steering gear is removed from the bottom of the car on all series as follows:

1. Disconnect battery.
2. Remove steering wheel.
3. Remove toe board plate screws.
4. Loosen four lower-to-upper steering jacket tube screws.
5. On Series 10 and 20, remove pitman arm. Support engine at front and remove front engine support cross member. Mark location of turning radius stop plate, then remove plate. Unfasten steering gear from its mounting and remove from under car.
6. On Series 80, remove left front wheel. Mark location of turning radius stop plate and remove plate. Remove pitman arm nut. Loosen steering gear housing attaching

Fig. 4 Layout of steering knuckle and pin parts.

screws and then remove pitman arm with a puller. Remove left exhaust manifold. Remove power steering hose bracket at left front engine support. Support engine at front and remove left front engine support mounting bracket. Remove front cross member with stabilizer bar attached. Unfasten steering gear and lower to floor.

MANUAL STEERING GEAR REPAIRS

1958-62 (Except American) Disassemble, Fig. 5

1. Rotate steering worm until nut is in center of travel.
2. Remove sector shaft nut.
3. Use puller to remove pitman arm.
4. Remove side cover screws and remove side cover and sector shaft from housing.
5. To remove side cover from sector shaft, turn adjuster screw in end of sector shaft down through cover.
6. Remove screws and take out end cover with worm bearing, outer race and thrust washer.
7. To remove lower worm bearing, outer race and thrust washer from cover, loosen worm bearing adjuster screw lock nut and turn screw in through cover.
8. Grasp lower end of steering worm and draw steering shaft and nut out of steering housing. *Be sure to keep shaft in horizontal position so that nut does not move against stops at any time, causing damage to ball return mechanism.* Disassembly of worm nut is not recommended.

Fig. 5 Recirculating ball and nut type steering gear. 1958-62 (Except American)

Fig. 6 Worm and roller type steering gear. All 1955-57 and 1958-62 American

Assemble

1. Install worm shaft and nut assembly in gear housing, keeping ball nut away from stops on worm.
2. Install worm bearing adjusting screw with lower worm bearing, outer race and thrust washer in end cover.
3. Install end cover and attaching parts on gear housing, making sure bearings seat properly.
4. Tighten worm bearing adjusting screw until a slight drag is felt on bearings. Do not tighten lock nut.
5. Install pitman arm.
6. Install sector shaft and adjusting screw inside cover.
7. Rotate steering column until ball nut is in center of travel so that center tooth on sector shaft will enter space on nut.
8. Install side cover and sector shaft in gear housing.
9. Tighten sector shaft adjusting screw until a slight drag is felt on bearing but do not tighten lock nut.
10. After steering gear is installed in car, adjust as outlined below:

Adjustments

1. Disconnect steering relay rod from pitman arm.
2. Loosen sector shaft lash adjuster screw a few turns to relieve load

from bearings.
3. Turn steering wheel in one direction until stopped by gear, then back away about one turn.
4. With a spring scale hooked to rim of steering wheel, measure pull required to keep wheel in motion; this should be ¼ to ¾ lb. If not within these limits, adjust worm bearings as follows:
5. Loosen worm bearing adjuster lock nut and turn adjuster until there is no perceptible end play in worm. Check pull at wheel rim, readjusting as required to obtain proper pull. Tighten lock nut and recheck pull.
6. After worm bearing adjustment is completed and all mounting bolts tightened, adjust sector shaft end play.
7. With steering wheel in straight-ahead position, turn lash adjuster screw clockwise to remove all lash and tighten lock nut.
8. Check pull at rim of steering wheel, taking highest reading on scale as wheel is turned through the central or straight-ahead position. This should be between ⅞ and 1½ lbs. *If more than 1½ lb., turn lash adjuster screw counterclockwise, then come up on the adjustment in a clockwise motion.*
9. Tighten lock nut and recheck pull.

1955-57 & 1958-62 American

In this type steering gear, Fig. 6, the worm is integral with the steering shaft and is supported on each end by opposed tapered roller bearings. The triple tooth roller is attached to the roller shaft by means of a steel shaft. Two needle bearing assemblies are installed between this shaft and the roller. (Some models have a two tooth roller shaft), Fig. 6.

The roller shaft is mounted in the steering gear housing on two needle bearing assemblies which are pressed into the housing. The housing cover is attached to the housing by four cap screws. An adjustment screw, mounted in the cover, controls roller shaft end play and worm and roller mesh adjustment.

The steering wheel and roller shaft arm (pitman arm) are splined to the steering shaft and roller shaft respectively. Both the pitman arm and steering wheel have master splines to insure correct installation.

Worm End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen four cover screws about ⅛".
3. Use a knife to separate the top shim, passing the blade all the way around between the shims, being careful not to damage the remaining shims.
4. Remove one shim at a time between inspections to remove the end play.
5. The adjustment is correct when there is no end play and no stiffness in the steering gear throughout the complete range of its travel.

Roller Shaft End Play, Adjust

1. Turn the steering gear to either extreme and back off ⅛ of a turn.
2. Gripping the pitman arm at the hub, the roller shaft should rotate freely without a particle of end play.
3. If end play exists, adjust as required by means of the roller shaft adjusting screw in the side cover.
4. Be sure to tighten the lock nut securely and inspect for end play and free rotation throughout the entire range of steering gear travel.

Worm & Roller Mesh, Adjust

1. Loosen the roller shaft adjusting screw lock nut.
2. With the steering gear in its central position (drag link disconnected) tighten the roller shaft adjusting screw just enough to remove play between the roller shaft roller tooth and worm.
3. Check this by the amount of play felt at the pitman arm. It is better to leave a slight amount of play at this point than to tighten too much.
4. If tightened beyond the point where the lash is removed, serious results will occur which will cause poor steering operation.
5. Tighten the adjusting screw lock nut.

Fig. 7 Power steering power cylinder assembly

POWER STEERING

On Car Adjustments

Adjustment of belt tension and bleeding of the system are the only two "on the ear" adjustments which can be made.

Belt Tension

Adjust the belt so it does not deflect more than ¼". This is done by loosening the belt pivot and adjusting bolts on the pump mounting bracket to allow movement of the bracket in its adjusting slot.

Bleeding Systems

To bleed the system, raise front wheels and run engine at idling speed until normal operating temperatures are obtained. Then accelerate the engine and turn front wheels to right and left several times until bubbles in reservoir disappear. *Do not hold wheels against stops.* Always recheck and replenish fluid in reservoir after bleeding.

Fluid Pressure Test

A fluid pressure test will show whether the pump or some other unit in the power steering system is causing trouble. Connect an oil pressure gauge in the main oil line at the control valve assembly. Start the engine and allow the oil to circulate for several minutes to warm the oil.

1. Turn the wheels against the curbing or other obstacle and hold tension on the wheel. The oil pressure should be 500-800 psi on 1956-57 models, 650-900 psi on 1958-59 models, 800-900 psi on 1960-61 models with Roll type pump and 850-950 psi on 1960-61 models with Slipper type pump.
2. Turn the wheel in the opposite direction and note the reading. If there is a variation between the left and right turns, internal leakage is evident. If the pressure is low, stop the engine and disconnect the gauge from the valve and cap the pressure line.
3. Restart the engine and note the reading. If the pump is operating properly the pressures will be as noted in Step 1. If the pressure is low the pump belt or fan belt may be slipping. With belt tension correct and there is low pressure, the trouble exists in the pump. *Do not run the last check for a period longer than is necessary to obtain a steady pressure reading.*

Pump Removal

Remove the fan belt and place a suitable container under the pump. Disconnect the pressure and return hoses, capping the outlets to prevent loss of oil in the power steering unit. Unfasten and remove pump from engine.

Pump, Install

Position the pump on the engine and install and tighten the bolts securely. Connect the pressure and return hoses, taking care to tighten the pressure hose evenly when forcing the outlet fitting into place. Tighten the drive belt so that not more than ¼" deflection exists. Fill the reservoir to the bottom edge of the filler neck and bleed the system as described earlier.

Power Cylinder Removal

1. Disconnect the oil hoses, the piston rod from the side sill bracket, and the tie rods from the cylinder and valve assembly.
2. Remove the pitman arm stud nut and roll pin, washer, cushions and spacers.
3. Remove the cylinder and valve assembly from the pitman arm stud. If necessary to overhaul power cylinder, refer to Fig. 7.

Power Cylinder, Install

1. Install the valve housing end of cylinder on the pitman arm.
2. Tighten the inner nut on the stud until there is sufficient tension on the rubber cushions to prevent rattles and grease leakage and still permit free movement of the stud. *Overtightening the stud will cause poor recovery from turns and binding when steering. Looseness may result in shimmy.*
3. When the stud nut is correctly adjusted, the locking roll pin should be installed.
4. After the cylinder has been installed in the car, and the hoses connected, fill the pump reservoir and bleed the system as outlined previously.

Control Valve, 1956-58

If the control valve has been disassembled the centering adjustment is made as follows:

The screw plug in the valve housing may be turned in or out 1/6 of a turn at a time, road testing after each adjustment. The plug should not be adjusted more than ½ turn in either direction. If the adjustment can not be made with a ½ turn, the cylinder and valve should be replaced.

Turn the plug *IN* if:
- Left turn is too hard
- Right turn is too easy
- Poor recovery from right turns, but good recovery from left turns
- Car wanders to the right

Turn the plug *OUT* if:
- Right turn is too hard
- Left turn is too easy
- Poor recovery from left turns, good recovery from right turns
- Car wanders to the left

Control Valve, 1959-61

If necessary to adjust the valve spool assembly for correct centering, turn piston rod end plug *OUT* and turn pitman arm end plug *IN* the same amount about ½ turn at a time for the following conditions:
- Left turn is to hard
- Right turn is too easy
- Poor recovery from right turns, but good recovery from left turns
- Car wanders to the right

Turn pitman arm end plug *OUT* and piston rod end plug *IN* the same amount about ½ turn at a time for the following conditions:
- Right turn is too hard
- Left turn is too easy
- Poor recovery from left turns, but good recovery from right turns
- Car wanders to the left

After final adjustment, tighten end plugs securely to 50 ft. lbs.

Instruments, Radio & Windshield Wiper

INSTRUMENTS

1955 Rambler & 1958-60 American

To remove the speedometer and instrument cluster, disconnect wiring and speedometer cable from rear of instrument cluster. Then remove three brackets retaining cluster to rear of panel. The speedometer and other instruments contained in the cluster are removed by unfastening the lens bezel and removing lens and two screws.

1956-59 Except American

The instrument panel is fastened to the front body pillars by two cap screws on each side. The panel is fastened along the top of the dash panel by sheet metal screws under the finishing moulding.

1960-61 Rambler; 1961 American

To remove the cluster, disconnect battery and remove wires and speedometer cable from instrument cluster. Unfasten instrument cluster (2 screws) and slide cluster downward out of two upper tab retainers and grommets. The cluster may then be removed and instruments serviced as required.

RADIO

1955 Rambler

1. Disconnect battery.
2. Remove heater switch and light switch mounting bracket.
3. Remove radio knobs and two retaining nuts located behind knobs.
4. Disconnect radio wire to battery at light switch.
5. Remove antenna lead.

6. Remove two screws at sides of radio and remove radio and speaker from under dash.

1956-57 Rambler

1. Disconnect battery.
2. Disconnect radio at fuse.
3. Disconnect antenna lead.
4. Remove radio knobs and shaft mounting nuts.
5. Remove radio mounting bolts and take radio out from under dash.

1958-60 American

1. Unfasten instrument switch panel from lower panel (2 screws).
2. Pull radio knobs off shafts.
3. Remove dial indicator pointer.
4. Disconnect radio power lead at fuse case and the antenna from right side of radio.
5. Remove nuts from radio control shafts.
6. Move radio toward front of car away from instrument panel, and remove.

1960-61 Except American

1. Disconnect battery and remove antenna lead from radio.
2. Disconnect power lead from radio and unplug radio-to-speaker cable.
3. Pull off control knobs and control shaft bushing nuts.
4. Remove screw from rear radio brace.
5. Remove radio toward back and down from instrument panel.

1961 American

1. Remove radio control knobs.
2. Remove radio overlay (2 screws).
3. Remove two vertical screws holding radio to dash.
4. Unplug antenna, power and speaker leads and lower radio from dash.

WINDSHIELD WIPER

1961 American

The wiper motor is mounted with two machine screws to a plate which in turn is fastened with four sheet metal screws to the dash panel under the instrument panel.

1. Remove radio to provide access to wiper motor and mounting plate.
2. Disconnect pivot shaft links from motor arm studs by removing spring clips.
3. Remove motor mounting plate-to-dash screws and remove motor and mounting plate as a unit.
4. Disconnect control cable from motor after lifting off plastic cover, and disconnect wiper hose.
5. At time of installation be sure mounting plate to dash is properly sealed as well as motor to mounting plate seal.

1955 Rambler; 1958-60 American

1. To remove the wiper motor, unhook the link to the motor retainer and remove link.
2. Release motor from mounting bracket (2 screws) and remove hose.
3. Loosen screw and lift control cable and conduit from motor control valve.
4. *When connecting the cable and conduit to the motor and valve, the conduit must not protrude beyond its mounting to allow for full travel of wire and valve.*

1956-61 Rambler

1. To remove wiper motor, first open heater control valve and drain about two quarts of fluid from radiator to lower coolant level.
2. Remove heater core.
3. Remove rain baffle below motor to make motor mounting screws accessible.
4. Remove link to motor retainer clips and link.
5. Disconnect control conduit and vacuum tube from motor and remove motor attaching screws.
6. *When installing motor, control cable must be checked to insure full travel of valve to open and closed position.*

ENGINE, REPLACE

L Head Six

For most service procedures where it is necessary or desirable to remove the engine, it is best to disconnect it at the junction of the engine block and clutch housing or converter housing. The clutch assembly would then be removed as a part of the engine. On models equipped with Automatic Drive, the torque converter should be disconnected from the engine drive plate so that the torque converter will remain on the transmission splines when the engine is removed.

However, if a different cylinder block is to be installed, the clutch housing or converter housing can be removed with the engine after disconnecting the propeller shaft at the transmission and removing the transmission. The clutch housing alignment can then be checked before the housing and engine are reinstalled.

1955-62 V8 Engines

For most service procedures where removing the engine from the car is necessary or desirable, it is best to disconnect it at the clutch or torque converter housing. However, if a different cylinder block is to be installed, it will be necessary to recheck the clutch housing alignment, and therefore the clutch housing should be removed with the engine. If the clutch housing is not properly aligned, the car will probably slip out of high gear.

Overhead Valve 6 cylinder engine

On cars with Air Conditioning, remove the compressor mounting bracket and compressor as an assembly *without disconnecting refrigerant hoses*. Move the assembly to a position on the front of the right front fender, being careful to keep the compressor crankcase lower than the compressor cylinder head so that oil will not leak into the chamber above the compressor pistons.

CYLINDER HEAD, REPLACE

Overhead Valve Six

1. Drain cooling system and remove upper radiator hose.
2. Remove rocker arm cover.
3. Remove spark plugs.
4. Remove manifold and carburetor as a unit.
5. Remove rocker arm shaft assembly.
6. Lift out push rods.
7. Unfasten and remove head.
8. Reverse removal procedure to install head and tighten head bolts in the sequence shown in Fig. 1 to the torque listed in the *Engine Tightening Chart*.

L Head Six

1. Drain cooling system and remove water outlet, thermostat and upper radiator hose.
2. Remove air cleaner.
3. Remove spark plugs.
4. Disconnect or remove any linkage tubes, wires, etc. attached to head.
5. Unfasten and lift off cylinder head.
6. Reverse removal procedure to install the head and tightening head bolts in the sequence shown in Fig. 2 to the torque listed in the *Engine Tightening Chart*.

V8 Engines

1. Drain radiator and remove air cleaner.
2. Disconnect linkage, tubes, wires, etc., attached to cylinder head being removed.
3. Remove intake manifold and carburetor as a unit.
4. Remove generator and battery if necessary.
5. If air conditioned, *remove compressor without disconnecting refrigerant hoses.*
6. Remove exhaust manifold bolts and pull manifold away from head.
7. Remove rocker arm shaft assembly and push rods.
8. Unfasten cylinder head and lift off.
9. Reverse removal procedure to install head and tighten bolts in the sequence shown in Fig. 3 to the torque listed in the *Engine Tightening Chart*.

Studebaker V8 engine

ROCKER ARMS

6 Cyl. Engines

1. Before disassembly, mark the rocker arms, brackets and rocker arm shaft so that they can be reassembled in the original positions.
2. Hold rocker assembly and press in on one of the shaft end brackets and remove cylinder head capscrew from the end bracket.
3. Gradually release the compression of the spring and carefully remove the bracket, spacer, first rocker arm, compression spring and the next rocker arm from the shaft.
4. Proceed in the same manner to strip the shaft of the remaining parts.
5. Except when new parts are used, install all rocker arms and brackets on the shaft in the original positions.

Fig. 1 Cylinder head tightening sequence. Overhead valve six

Fig. 2 Head tightening sequence, 1955-60 Six

Fig. 3 Cylinder head tightening sequence. V8

Internal parts of Studebaker V8 engines

The two end brackets differ from the center brackets. *To insure correct installation and oil distribution, a flat is located on the front end of the rocker arm shaft.* Make certain that the oil holes and grooves in the shaft and oil holes in rocker arms and adjusting screws are clean. Clearance between rocker arms and shaft should be .0005″ to .0025″. If clearance is excessive, install new parts. Lubricate all parts with engine oil during assembly.

V8 Engines

1. Before disassembly, mark the rocker arms, brackets and shaft so they can be reassembled in their original positions.
2. Referring to Fig. 4, push in on the outer flat washer at one end of the assembly so that the spring washer is compressed, and remove the cotter pin.
3. Remove the washers and slip the end rocker arm off the shaft.
4. Holding the next rocker arm so that the spacer spring is compressed, remove cylinder head capscrew from the end bracket. Still holding the spacer spring compressed, slide the bracket off the shaft.
5. Gradually release the compression of the spring and remove the next rocker arm and space spring.
6. Proceed in the same manner to strip the shaft of the remaining parts.
7. Except where new parts are used, install parts on shaft in reverse order of removal. Before assembly, test rocker arm spacer springs; they should require from 9½ to 10½ lbs. to compress each spring to $2\frac{1}{32}$″. A spring that does not test within these limits should be replaced. Make certain that the oil holes and grooves in rocker arm shaft and oil holes in rocker arms and adjusting screws are clean. Clearance between rocker arms and shaft should be .0005″ to .0025″. If clearance is excessive, install new parts. Lubricate all parts with engine oil during assembly.

VALVES, ADJUST

Overhead Valve Engines

A self-locking adjusting screw is used between the rocker arm and push rod for valve clearance adjustment. A torque of at least 30 inch lbs. should be required to turn the screw when the threads are engaged on both sides of the groove. Check with a spring scale in a manner similar to that shown in Fig. 7. The pull on the spring scale should be at least 30 inch lbs.

If the cylinder head cap screws are to be tightened, always complete the tightening process before adjusting valve clearances.

Adjust the clearances to the specifications given in the *Valve Specifications* chart. To set the clearance with the engine cold (at room temperature), turn the crankshaft until No. 1 piston is on

Engine lubrication. V8-232, 259 and 289 engines

Fig. 4 Rocker arm assembly. V8 Engines

Fig. 6 Self-locking tappet adjusting screw. L head six

Fig. 7 Using spring scale to check tension on self-locking tappet adjusting screw. L head six

the compression stroke and the UDC 1-6 on the vibration damper is directly under the timing pointer. Then adjust the clearance for No. 1 cylinder valves to the specifications listed in the *Valve Specifications Chart.* Then turn over the engine and adjust the remaining valves in accordance with the firing order of the engine, Fig. 5.

L Head Six

The slotted adjusting screw, Fig. 6, of the valve lifter is self-locking. When an adjusting screw is replaced, the torque required to turn the screw should be measured. A torque of at least 2 lb. ft. should be required to turn the screw. This is approximately a 4-lb. pull at the end of a six-inch wrench with a spring scale attached as shown in Fig. 7.

The valve clearance should be set to the clearances given in the *Valve Specifications* chart and should be set with the engine cold (room temperature of 70°).

Fig. 5 Adjusting valves on overhead valve engines

Turn the crankshaft in the direction of normal engine rotation until the No. 1 piston is on the compression stroke and the ignition timing mark is in line with the timing pointer. Then adjust the valves for No. 1 cylinder.

To be sure that the valve lifter is on the base circle of the cam, remove the distributor cap and connect a single-contact timing light to the primary wire on the distributor and to a ground. Turn on the ignition switch and rotate the distributor until the breaker points open for No. 1 cylinder (bulb lights). Rotate the crankshaft until the bulb lights again and adjust No. 5 valves. Repeat this procedure, following the firing order of the engine.

VALVES, REMOVE

Overhead Valve Engines

1. Use a suitable valve spring compressor to remove the valve spring locks, Fig. 8. *The valve springs must not be compressed more than is required to remove the locks. If they are compressed until the coils bottom, the springs may lose as much as 10 to 15 lbs. tension.*
2. Release the valve spring compressor slowly and remove the parts from the valve.
3. Repeat the operation and strip the remaining valves.
4. Remove the valves from the head and place them in a board with numbered holes so that, if they are to be reused, they can be inserted in the original guide holes.
5. Referring to Fig. 9, install the damper on the closed coil end of the spring. Cupped side of seal goes toward top of valve guide.
6. The spring dampers should be inspected to be sure that the fingers are not bent out. The fingers must contact the sides of the springs to be effective.

L Head Six

To remove valves from these engines, take off the cylinder head and valve covers and use cloth to block off the holes in the valve chamber to prevent the valve locks from falling into the crankcase.

With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the locks. Then turn the crankshaft until those

Fig. 8 Removing valve keepers with the aid of special cylinder head holding tool

Fig. 9 Location of seal (1) and damper (2) on valve stem (3). Overhead valve engines

valves which are open are closed and remove the remaining valve locks.

Remove all valves and place them in a board with numbered holes so they can be identified as to the valve port from which they were removed.

VALVE SPRING INSTALLED HEIGHT

Overhead Valve Engines

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 10. If the assembled height is geater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve spring and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

Fig. 10 Checking installed height of valve springs. Overhead valve engines

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16", and since the acceptable valve head margin is approximately $\frac{3}{64}$" to $\frac{5}{64}$", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.

VALVE SPRING TESTING

Wash the springs with gasoline or other suitable solvent. Then examine them for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring pressure on a spring testing fixture, if one is available, Fig. 11. If a fixture is not available, at least check the free length of each spring by standing it alongside a new one. Any spring that does not conform to the specifications in the *Valve Data* chart within 10 per cent. should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded.

VALVE GUIDES

Overhead Valve Engines

Clean the valve guides with a wire guide brush, and clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads, as well as the gum which might have accumulated on the stems.

Check the valve stem-to-guide clearance with a dial indicator if one is available. Mount the indicator on the valve guide so that the button contacts the valve stem squarely and as near the end of the guide as possible. Then move the valve stem away from the indicator. Note the total clearance reading. If the guides are worn so that the reading exceeds .0035 in., new guides should be installed.

Fig. 11 Checking valve spring tension. All models.

The special Valve Guide Tool shown in Fig. 12 should be used to remove and install guides in these engines. When removing a valve guide, use the driver to drive the guide out of the cylinder head from the combustion chamber side.

When installing a guide, first coat the outside of the guide lightly with white lead. Then start the chamfered end of the guide into the head from the combustion chamber side. Place the installing plate on the face of the head as shown in Fig. 12 and drive in the guide until the shoulder of the driver contacts the bottom of the counterbore in the plate. The plate is marked "Intake" on one side and "Exhaust" on the other. Be sure the exposed mark of the plate corresponds to the valve guide being installed.

If the special tool is not available, carefully measure the position of the guides before removing them and drive the new ones in accordingly.

L Head Six

To check valve stem-to-guide clearance, take a new valve and place it in

Fig. 12 Showing special tool used to control position of valve guides when driven in place. Overhead valve engines

each valve guide and feel the clearance by moving the valve stem back and forth. If this check shows excessive clearance (over .0035 in.) it will be necessary to replace the guide. If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

If it is necessary to replace valve guides, the old guides can be driven down and out of the valve chamber. A special driver is available for this work. However, in lieu of the driver, the guides can be pulled out of the block by using a suitable piece of pipe together with a long bolt and suitable washer.

Be sure the new guides are driven to the correct position in the block. This can be determined by measuring the position of the old guides before they are removed.

VALVES, GRIND

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced.

Inspect the valve seats for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed before refacing the seats if the equipment used has a valve guide pilot.

The valve seat width after refacing should measure $\frac{1}{16}''$ to $\frac{3}{32}''$. The width may be checked by placing a scale across the face of the seat.

VALVE LIFTERS

Overhead Valve Engines

A straight barrel type lifter is used. To remove the lifters, take off the cylinder heads and push rods as outlined previously. Then remove the three capscrews that retain the valve lifter chamber cover and breather pipe and lift off the cover and pipe.

Take out the valve lifters, keeping them in order so they can be replaced in the same bore from which they were removed.

Wash the lifters with clean gasoline or other solvent. Remove the carbon and sludge deposits from the oil holes. Inspect all lifters for excessive wear and replace where necessary.

L Head Six

Mushroom type lifters are used on all Champion engines which means that the oil pan and camshaft must be removed and the lifters taken out from below when lifters require replacement, Fig. 13.

TIMING GEAR COVER

V8 Engines

1. To remove the cover, drain cooling system and remove fan shroud and radiator.
2. Remove fan belt, and power steering belt (if equipped).
3. Remove fan blade assembly.
4. Remove water manifold.
5. Remove fuel pump.
6. Remove vibration damper and fan pulley hub.
7. Remove screws and take off cover.
8. On 1955-58 models, do not remove the self-tapping screws which hold the retainer plate. Remove the felt oil seal with an ice pick or other pointed tool and clean the recess in the cover carefully before installing a new felt seal.
9. Install the new seal and wet it with engine oil in the recess in the cover. Insert the crankshaft pulley hub through the seal to center it.
10. Install the cover but do not tighten the screws. Install the crankshaft pulley hub to locate the seal and cover properly; then tighten the cover screws.
11. Complete the installation in the reverse order of removal.

Fig. 13 Valve mechanism. L head six

Fig. 15 Timing gear installation. Six-Cylinder Engines

Six-Cylinder Engines

1. Remove radiator.
2. Remove vibration damper.
3. Remove crankshaft fan pulley.
4. Remove screws and take off cover.
5. Pick out the old oil seal and clean out the recess in the cover.
6. Install a new seal in the cover, using the hub of the crankshaft pulley to seat it in the recess.
7. Install the cover, leaving the screws loose enough so that the cover can center itself as the crankshaft pulley is installed.
8. Press crankshaft pulley into position and securely tighten the cover screws.

TIMING GEARS

For correct valve timing, the gears should be assembled as shown in Figs. 14 and 15. Always use suitable puller and pusher equipment when removing and installing gears. This is particularly important in the case of camshaft gear as there is danger of loosening the welsh plug in back of the camshaft if the gear is driven on with hammer blows.

CAMSHAFT, REPLACE

V8 Engines

1. Turn the crankshaft until the timing marks show the IGN mark directly under the pointer on the timing gear cover and the distributor rotor is in the No. 6 firing position. In this position the timing mark on the camshaft gear is properly aligned between the marks on the crankshaft gear, Fig. 14.
2. Remove radiator and water pump.
3. Remove rocker arms and push rods.
4. Remove carburetor and intake manifold.
5. Remove breather pipe and valve lifter cover and take out valve lifters.
6. Remove fuel pump.
7. Remove timing gear cover.
8. Turn camshaft just enough to expose thrust plate retaining screws and remove the screws. Then turn the gears back to align the marks of the two gears.
9. Remove camshaft and gear as a unit, being careful not to damage the camshaft bearings.
10. Remove the gear from the camshaft with a puller.
11. Install a new camshaft gear on the camshaft, install the assembly in the engine and align the timing gear marks as shown in Fig. 14.
12. Check the gear backlash, which should be .001-.003". Install the camshaft thrust plate screws and complete the installation in the reverse order of removal.

Six-Cylinder Engines

To remove the camshaft, take off the radiator and all necessary sheet metal. Remove vibration damper and pulley. Remove the timing gear cover and

Fig. 14 Valve timing marks for No. 6 cylinder. V8 Engines

screws which fasten the camshaft thrust plate to the cylinder block. Take off the manifolds, cylinder head, fuel pump, oil pump, oil pan, oil pump drive shaft and valve covers.

If removal of the valves is not intended, raise the lifters and keep them up with spring-type clothespins or metal supports so they won't interfere with the camshaft as it is being withdrawn.

PISTONS & RODS, REMOVE

After removing the cylinder heads and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod caps and push the pistons and rods out through the top of the cylinders, using care to prevent the big end of the rods from damaging the crankshaft or cylinders.

Make sure the rods and pistons are properly numbered so they can be reinstalled in the original locations. It is advisable to install caps on rods to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

V8 Engines

Pistons should be assembled to the connecting rods so that the oil squirt holes are on the same side as the unslotted side of pistons, Fig. 16. And when installed in the cylinders the T-slot side of all pistons should be toward the left side of the engine.

Six-Cylinder Engines

When correctly assembled the oil squirt hole in the connecting rod will be on the camshaft side of the engine with the T-slot side of the piston facing away from the camshaft.

PISTONS

Standard size service pistons are high limit or maximum diameter; therefore, they can usually be used with a slight amount of honing to correct slight scoring or excessive clearances in engines having relatively low mileages. Service pistons are also furnished in .005, .010, .015, .020 and .030 in. oversizes.

Before a honing or boring operation is started, measure all new pistons with a micrometer at points exactly 90 degrees away from the piston pin. Then select the smallest piston for the first fitting. The slight variation usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

It is very important that refinished cylinder bores are trued up to have not more than .0005 in. out-of-round or taper. Each bore must be final honed to remove all stone or cutter marks and provide a smooth surface. During final honing, each piston must be fitted individually to the bore in which it will be installed and should be marked to insure correct installation.

After final honing and before the piston is checked for fit, each bore must be thoroughly washed to remove all traces of abrasive and then dried thoroughly. The dry bore should then be brushed clean with a power-driven fibre brush.

Both the piston and cylinder block must be at the same temperature (room temperature of 70 degrees) when the piston is checked for fit in the cylinder bore. Therefore, the cylinder should be allowed to cool after boring or honing and before the piston fit is checked. This is important because a difference of 10 degrees between the temperature of parts is sufficient to produce a variation of .0005 in.

PISTON RINGS

When new piston rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled but without increasing the bore's diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

Fig. 17 Checking bearing clearance with Plastigage. All models

Fig. 16 Correct assembly of pistons to rods. V8 Engines

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with either end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of rings carefully with a smooth file.

PISTON PINS

Service piston pins are available in standard and .0025 and .005 in. oversizes. When fitted correctly in the piston, pins should require a light finger push with parts at room temperature of approximately 70 degrees.

V8 Engines

To remove the piston pin, remove the lock nut and star washer from the clamp screw. Install and tighten the lock nut on the other end of the clamp screw, which will loosen the clamp screw in the rod. Remove the screw from the rod and slide the piston and rod off the pin.

To install the pin, slide the piston and rod into position. But before inserting the clamp screw, be sure the solid side of the

piston is to the squirt hole side of the rod.

If the connecting rod is a new one and hasn't been marked, it should be checked to determine whether it is a left or right bank rod. The rods are offset at the crankpin end and can be identified as shown in Fig. 16.

Install the piston pin clamp screw so that the nut will be installed on the T-slot side of all pistons. Be sure the flat surface of the clamp screw mates with the flat surface of the piston pin, otherwise the pin will work loose in service.

Six-Cylinder Engines

On these engines the piston pin is locked in the rod in the same manner as for V8 engines. However, on connecting rods 1, 3 and 5, the clamp screw nut is installed on the T-slot side of the piston. On Nos. 2, 4 and 6, the nut is installed on the solid side of the piston.

When installing the clamp screw regardless of the rod number, hold the rod with its offset to the left and insert the screw from the front. This will locate the lock nut on the correct side with relation to the piston.

ROD BEARINGS

Connecting rod bearings can be replaced without removing the connecting rod assembly by removing the cap and replacing the upper and lower bearing halves. The clearance between the bearing and crankshaft can be measured with Plastigage as follows:

1. Remove bearing cap and wipe oil from crankshaft and bearing.
2. With crankpin at approximately bottom dead center, place a piece of Plastigage in the center of the cap, Fig. 17.
3. Reinstall the cap and tighten to the torque value given in the *Engine Torque Specifications* table.
4. Remove the bearing cap and determine bearing clearance by comparing the width of the flattened Plastigage at its widest point with the graduation on the Plastigage envelope. The number within the graduation on the envelope indicates the clearance in thousandths of an inch, Fig. 17. If clearance is excessive, install a new bearing.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005″ to .015″ cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed. *Be sure to remove cardboard.* To install new bearings, proceed as follows:

Fig. 18 Installing neoprene seals in bearing cap groove. All models

1. Remove bearing cap and worn lower shell.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque value given in the *Engine Torque Data* table.

Service Note, L Head Six

The small amount of clearance between the front main bearing cap and the crankshaft cheek-to-engine front plate makes it necessary to follow a specific procedure in removing the front main bearing cap.

To remove the bearing cap, first remove the gasket from the engine front plate. Turn the crankshaft until the No. 1 connecting rod bearing journal is at approximately a 5 o'clock position (partly down and toward the camshaft). Unfasten the bearing cap and separate it from the block and swing the end that is away from the camshaft toward the rear of the engine, crossing the crankshaft cheek. Turn the free end of the bearing cap toward the cylinder bore and at the same time bring the other end over the crankshaft.

To install, reverse the procedure.

Fig. 19 Installing crankshaft rear oil seal

CRANKSHAFT OIL SEAL

Oil sealing at the rear main bearing is controlled by a Brummer oil seal installed around the crankshaft journal, wood filler blocks between the sides of the main bearing cap and block, and Neoprene seals between the bearing cap face and block.

It is not necessary to remove the engine from the chassis to replace the Brummer oil seal.

1. Remove rear main bearing cap and the old seal.
2. Wash bearing, blow dry and wipe clean.
3. Loosen intermediate bearing caps about two turns to give additional clearance between rear journal and block.
4. Insert Neoprene seals in cross grooves of rear bearing cap as shown in Fig. 18.
5. Place cap with seals downward on a flat surface and, while pressing on cap, use a sharp knife or razor blade to cut protruding ends of seals flush with sides of cap.
6. Blunt sharp edge of flange at rear of block on which Brummer seal is mounted, Fig. 19. Use flat side of screwdriver or similar tool.
7. Install new Brummer seal *dry.*
8. Parting line or split of two seal halves should be *assembled horizontally.* This will guard against initial distortion of or damage to seal during completion of the installation.
9. Install bearing cap and tighten screws to specified torque; also torque intermediate bearing caps which were previously loosened.
10. Install two wood filler blocks between sides of bearing cap and block, being sure blocks are not damaged or split during the installation.
11. Complete the job and run engine for 45 minutes and check for oil leaks.

OIL PAN

1955 Champ. & 1956-58 Sixes

1. Drain oil and remove level gauge.
2. On long wheelbase models, swing wheels to the right to move the steering bellcrank out of the way.
3. On shorter wheelbase models, disconnect tie rods and reach rod from steering bellcrank. Remove retaining pinch bolt and bellcrank from shaft.
4. Remove pan screws and lower oil pan.

1955-58 V8

1. Drain oil and remove level gauge and oil level gauge adapter tube.

Fig. 20 Ignition details. V8 Engines

2. Disconnect one battery cable and remove starting motor.
3. On models with 120½" wheelbase (except Land Cruisers), swing wheels to the right to move steering bell crank out of the way.
4. On models with 116½" wheelbase and Land Cruisers, remove steering bell crank and exhaust cross-over pipe.
5. On all models, remove attaching screws and drop oil pan.

1959-62 Sixes

1. On Hawk models, swing wheels to the right to move steering bellcrank out of the way. Unfasten oil pan and remove from car.
2. On all models except Hawks, disconnect tie rods and reach rod from bellcrank. Remove retaining pinch bolt and remove bellcrank from shaft. Remove attaching screws and drop oil pan.

1959-62 V8's

1. Remove oil level gauge and adapter tube by removing head bolt which retains tube clamp.
2. Disconnect one battery cable.
3. Drain oil from crankcase.
4. Remove starting motor.
5. On Hawk models, swing wheels to the right to move steering bellcrank out of the way. Then unfasten and remove oil pan.
6. On all models except Hawks, remove steering bellcrank assembly, exhaust crossover pipe and exhaust connection. Unfasten and remove oil pan.

OIL PUMP REPAIRS

Important—On all six-cylinder engines, before removing the oil pump, crank the engine to bring No. 1 piston to its firing position, which is when the ignition mark on the vibration damper or flywheel is in line with the pointer. If possible, leave the engine in this position while the pump is off in order to obtain correct ignition timing. However, if the engine is disturbed while the pump is off, return it to the No. 1 firing position before attempting to install the pump.

1955 Champ. & 1956-62 Sixes

To remove the oil pump and drive gear the crankshaft must be turned away from the No. 1 top dead center position to provide sufficient clearance between the cylinder block and the crankshaft center counterweight. If it is necessary to remove the oil pump drive shaft and gear, the oil pan must be removed. Note the position the crankshaft is in when the oil pump shaft and drive gear is removed because this is the position the crankshaft must be in when the shaft and gear are again installed.

When installing the oil pump shaft and drive gear, first position the crankshaft so the oil pump shaft will enter the block. Then turn the crankshaft to the No. 1 top dead center position and push the oil pump shaft and drive gear out of engagement with the camshaft. Turn the shaft and gear until the keyway in the shaft points toward the bottom of the engine. Then draw the oil pump drive gear into engagement with the camshaft gear. As the two gears engage, the keyway in the oil pump shaft will turn toward the rear of the engine. This provides the correct location for distributor setting and ignition timing.

V8 Engines

Removing the pump from these engines does not effect the ignition timing. After removing the oil pan as previously outlined, remove the two pump retaining nuts and slip the pump from the mounting studs.

RADIATOR

1955

1. Drain cooling system and disconnect radiator inlet hose.
2. Remove fan blades.
3. Remove wiring junction block and horn relay from fan shroud.
4. Pry open wiring harness clips and move harness out of the way.
5. Remove four cap screws holding fan shroud to radiator support and remove fan shroud.
6. Unfasten radiator from its support and lift it out.

1956-62

1. Drain cooling system.
2. Disconnect battery.
3. Tie up hood.
4. Remove horn relay and headlamp junction block screws and free wires from top of shroud.
5. On B, H and J models, remove gasoline pipe screw.
6. If car has power steering, free upper hose from hose support.
7. Remove fan blades.
8. Remove upper and lower hose.
9. Unfasten and remove radiator.

WATER PUMP REPAIRS

Six-Cylinder Engines

1. To remove the pump, drain the cooling system.
2. Remove fan shroud (if equipped).
3. Remove fan belt, fan blades and pulley.
4. Disconnect Climatizer hose (if equipped).
5. Remove generator adjusting arm, if necessary.
6. Disconnect radiator outlet hose.
7. Unfasten and remove water pump.
8. To disassemble, remove bearing lock ring. Place pump in arbor press and remove shaft, bearing and hub assembly by pressing arbor through impeller and out through front of housing. Then press shaft out of hub.
9. If the thrust seal surface in the housing has become rough, it should be refaced with a water pump facing tool. In reassembling the pump, always use a new seal assembly and impeller. When installing the impeller, there should be .015" to .031" clearance between the impeller and housing. Rotate the shaft when checking the clearance.
10. Install the pump in the reverse order of removal.

V8 Engines

1. To remove the water pump, drain cooling system.
2. Remove fan belt, fan and pulley and fan shroud.
3. Unfasten and remove water pump from water manifold.
4. To disassemble, remove the bearing lock ring. Place pump in an arbor press and push hub, shaft and bearing out of impeller and cover. Then press shaft and bearing out of hub.
5. If the thrust seal surface in the housing has become rough, it should be refaced with a water pump facing tool. Use a new fan hub to insure a tight fit on the shaft. Press the hub on the shaft so it is flush with the end of the shaft. Insert the shaft in the housing and install the bearing lock ring. Then install a new seal assembly in the impeller and press the impeller on shaft so it is flush with end of shaft. Clearance between impeller and cover should not exceed .090".
6. Install pump in reverse order of removal.

DISTRIBUTOR, REPLACE

1. Before removing distributor on V8

models, turn crankshaft until IGN mark on vibration damper is directly beneath pointer, and distributor rotor is in line with No. 1 spark plug terminal of cap.
2. On all models, remove distributor cap.
3. On V8 models, remove air cleaner.
4. On all models, disconnect cable from coil tower. Then remove spark plug cables, cable brackets and distributor cap as a unit.
5. Remove cable from center terminal of distributor.
6. Disconnect vacuum advance pipe.
7. Remove distributor clamp and lift out distributor.

Installation, Six Cylinder

1. Insert distributor shaft in cylinder block opening and engage slot in end of shaft with tongue of oil pump drive shaft.
2. Install distributor clamp. Before tightening clamp screw, position clamp so that center of octane selector scale is aligned with scribe mark on mounting pad.
3. Connect wires, vacuum advance pipe and secure cap.
4. Set timing as outlined below.

Installation, V8 Engines

1. Be sure IGN mark is directly under pointer on gear cover.
2. Position distributor with rotor pointing toward front of engine with vacuum advance unit pointing to front and slightly to the right.
3. Turn rotor approximately 30° clockwise and insert oil pump drive shaft and coupling into cylinder block opening. When teeth on distributor shaft gear contact teeth on camshaft gear, the rotor will be turned counterclockwise and, as the teeth mesh, the tongue on the oil pump drive shaft will enter the groove of the oil pump shaft. This will permit the distributor to seat on the block, and the rotor will have to be turned to point directly at the No. 1 terminal of the distributor cap, Fig. 20. Very slight misalignment may cause difficulty in engaging oil pump drive shaft tongue with groove of oil pump shaft. After gears are meshed, engine may be cranked to secure proper alignment. Maintain light pressure on distributor while cranking engine to facilitate engagement.
4. Complete the installation and time the ignition as outlined below.

IGNITION TIMING

1. When distributor is installed it should be positioned so that the contact points will just start to open and the rotor will be pointing directly at the No. 1 terminal in the distributor cap when the index line nearest the IGN mark on the vibration damper is directly under the pointer on the timing gear cover.
2. Before checking the timing with the engine running, disconnect the vacuum advance pipe at the carburetor and install a temporary plug in the carburetor. This will prevent the possibility of the vacuum advance holding the breaker plate from returning to the full retard position.
3. Use a power timing light and, if rubber caps cover the spark plug terminals, an adapter will have to be used on the No. 1 spark plug to provide a terminal for attaching the timing light.
4. With the engine running at hot idle speed, the timing mark should show the index mark nearest the IGN mark to be directly under the pointer. If it does not, loosen the distributor clamp nut and turn the distributor as required to obtain the correct setting.
5. Remove the temporary plug from the carburetor and connect the vacuum advance pipe.

Fig. 21 Cutaway view of supercharger. 1957-58 Golden Hawk

SUPERCHARGER

1957-58 Golden Hawk

The supercharger, Fig. 21, is of the single-stage, centrifugal type. It is a five-pound boost, full-pressure system which crams about a 30 per cent greater amount of fuel and air mixture into the combustion chamber, resulting in high explosion pressures than under normal operating intake vacuum. The supercharger is driven through a variable rate pulley which produces maximum power during acceleration while permitting normal fuel economy at cruising speeds.

Drive power is taken from the engine crankshaft through a single "V" belt and the variable-ratio pulley fitted to the input shaft of the supercharger.

A planetary drive system is incorporated between the input and output shafts to increase the speed of the impeller. It is a ball bearing, friction-type system which eliminates the use of gears. Spring-loaded ball races automatically take up any wear that might develop in the drive.

The lubrication system is completely self-contained and does not require any connections to the engine lubricating system. An internal oil sump holds 8 ounces of Automatic Transmission Fluid. The piston-type oil pump works off a cam ground into the input shaft. A dipstick oil gauge, located in the bearing housing assembly, is marked to indicate the "safe" operating level and the "add oil" level of the lubricant in the sump.

Supercharger Testing

1. With the engine at rest or idling, the belt should be in the bottom of the pulley groove (high blower position).
2. With the engine running at approximately 1500 rpm, the belt should start to leave the bottom of the groove and begin to climb up.
3. With the engine running at 3500 rpm (no load) the belt should be running near the top of the pulley (low blower position).
4. With the engine at 3500 rpm (no load) manually operate the regulator kickdown switch. The belt should go immediately to the bottom of the pulley groove (high blower position). Releasing the kickdown switch should allow the belt to return immediately to the top (low blower position).
5. Remove the ⅜" pipe plug, located at the rear of the rear of the cover,

(normally used for setting the idle speed) and, using a low reading pressure gauge, connect it to the air chamber cover. Pressure at this point should indicate approximately 5 pounds at 3500 rpm with the kick-down switch closed (in high blower position).

6. Fuel pump pressure should be checked at idle by disconnecting the line at the air chamber base and hooking the gauge on the open line. A reading of 5½ to 7 lbs. should be recorded.

Supercharger Does Not Shift

If the variable-ratio pulley does not shift or operates sluggishly, check the following:

1. Spline may be burred.
2. Spline dirty and sticky.
3. Rough or gummy pulley.
4. Tension arm binding. It should be free on pivot pin and have a slight end play so washers will turn free.
5. Solenoid regulator not operating. An audible click should be heard with the ignition on each time the switch is depressed. The circuit should be connected to the 12-volt side of the ignition coil resistor.

Supercharger Boost Pressure Too Low

If the supercharger shifts okay and the pulley is functioning properly, check the following:

1. Improperly operating solenoid regulator.
2. Hose leakage between supercharger inlet and carburetor air chamber.
3. Carburetor air chamber leaking air —could be gaskets or leaking flapper valves.
4. Dirty air cleaner.
5. Malfunction of supercharger such as air leakage by seals, etc. Necessary to overhaul supercharger.

STARTER REPLACE

1955-58

Before the starter can be removed on Champion models the oil level gauge adapter and distributor must be removed.

On 1956 Golden Hawk remove the left exhaust pipe at the flange mounting.

1959-62

1. Disconnect one battery cable.
2. On six cylinder models, remove the oil level gauge and tube. Disconnect wires from starter, unfasten and remove starter from engine.
3. On V8 models, disconnect a cable from battery and the cable at the starter. Unfasten and remove starter from clutch or converter housing.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum passages in carburetor between choke housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck either in the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm up, combustion chamber deposits, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Move the valve up and down a few times to work in the oil. *Never use engine oil for this purpose as it will leave a residue which hampers valve operation.*

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

STROMBERG CARBURETOR ADJUSTMENTS

STROMBERG NOTES

THROTTLE RETURN DASHPOT

Supercharged Models — Adjust dashpot unit in bracket until plunger just breaks contact with tab on throttle lever. Mark position of dashpot relative to bracket, then turn dashpot 1¾ to 2 turns toward throttle lever.

CARBURETOR BALL CHECKS

Whenever it becomes necessary to dismantle a carburetor be sure to account for the ball check valves that may be found under pump plungers and compensating or power valves.

Fig. ①—WW float level. To adjust bend lip of float lever.

②—Close choke so that high step of fast idle cam contacts fast idle screw. Turn fast idle screw until the clearance specified exists between throttle valve and carburetor bore on idle port side.

Fig. ④—With choke valve fully closed and fast idle cam in fast idle position, one-half the diameter of the button at the end of the throttle stop screw should rest against the step of the fast idle cam. Adjust by bending choke lever ear.

Fig. ③—Hold choke valve lightly closed. Then open throttle until throttle lever stop rests against throttle body stop. Choke should be open the dimension specified between narrow side of choke valve and inner wall of air horn. Adjust by bending throttle lever ear.

CARTER NOTES

METERING ROD

AS—Metering rod should just bottom at wide open throttle. Adjust by bending metering rod arm.

WCFB—Metering rod adjustment must be made after pump setting. Back out throttle lever set screw to seat throttle valves in carburetor bores. Loosen metering rod arm clamp screw. With metering rods in place, press down on vacumeter link until metering rods bottom in casting. Holding rods down, revolve metering rod arm until finger on arm contacts lip of vacumeter link. Hold in place and tighten clamp screw.

Fig. ①—AS float level. Adjust by bending float lip.

Fig. ②—Pump arm on lifter link should parallel top of casting. Adjust by bending pump arm.

CARTER NOTES continued

Fig. ③—With choke valve closed there should be the clearance specified between lower edge of throttle valve and carburetor bore with fast idle link on high step of cam. Adjust by bending choke connector rod.

Fig. ⑤—WCFB float level. Adjust by bending float lever.

Fig. ⑦—With pump connector link in outer hole of pump arm and with throttle valves closed, flat on pump arm should parallel a straightedge placed across dust cover boss. Adjust by bending throttle connector rod.

Fig. ⑥—WCFB float drop. Adjust by bending stop tabs on float bracket.

Fig. ④—With throttle valve wide open there should be the clearance specified between top edge of choke valve and inner wall of air horn. Adjust by bending arm on choke trip lever.

Fig. ⑩—BBR1 float level. Adjust by bending lip of float lever.

⑧—With throttle closed, tighten fast idle adjusting screw on high step of fast idle cam until there is the clearance specified between throttle valve and carburetor bore (side opposite idle port).

⑨—With throttle valve wide open there should be the clearance specified between lower edge of choke valve and inner wall of air horn. Adjust by bending unloader lip on throttle shaft lever.

CARTER NOTES

continued

⑪—Pump plunger should travel distance specified with pump link in center hole of pump arm. Adjust by bending pump lifter link.

Fig. ⑫—WE float level. Adjust by bending float lever.

⑬—Pump plunger should travel distance specified. Adjust by bending throttle connector rod.

⑭—Hold choke valve closed, then close throttle. There should be the clearance specified between throttle valve and carburetor bore. Adjust by bending choke connector rod.

⑮—With throttle valve wide open there should be the clearance specified between lower edge of choke valve and inner wall of air horn. Adjust by bending arm on choke trip lever.

⑯—With choke valve tightly closed and fast idle screw on highest step of fast idle cam, there should be the clearance specified between throttle lever and lower tip of plunger shaft. Loosen locknut and turn adjusting screw as required.

Clutch and Transmission Section

CLUTCH PEDAL, ADJUST

1955-58

The clutch pedal should have from ½" to 1" free travel on all models except the Goldenhawk, which has 1½" free travel. On all models except Goldenhawk, adjust by loosening the lock nut on the rod connecting the clutch release shaft lever and remove clevis pin. Turn clevis to shorten or lengthen to obtain the desired result.

On the Goldenhawk, loosen the lock nut on the rod connecting the release shaft lever to operating shaft and turn the nut as required to obtain the desired adjustment.

1959-62

The clutch pedal should have ¾" free travel. A correctly adjusted brake pedal (free travel adjustment of ¼ to ⅜") is used as a reference point when adjusting clutch pedal free travel.

With the brake pedal correctly set (by means of the adjusting stop screw) adjust the clutch pedal to the same height. Turn the clutch pedal stop screw as required to bring the pedal to the same height as the brake pedal. *On cars with power brakes, adjust the clutch pedal pad location with the stop screw so that the distance from the top of the clutch pedal pad to the floor mat or carpet is 6¼ to 6½".*

Adjust length of overcenter clutch return spring by turning the nut so that the overall length of the spring is 10".

Adjust the clutch pedal-to-bellcrank rod to give ½" clearance between top end of bellcrank and body flange on front side of firewall. Loosen lock nut on rod connecting clutch operating bellcrank to the operating shaft lever. Turn the nuts to shorten or lengthen the rod to decrease or increase the pedal free travel as required to obtain a free travel adjustment of ½ to 1", measured at the pedal pad.

CLUTCH, REPLACE

1955

1. Disconnect battery.
2. On all six-cylinder models, remove oil level gauge and tube.
3. Take off starter without disconnecting wires and tie it out of the way.
4. On V8 models, remove starter.
5. On all models, remove floor plate and top clutch housing cap screws.
6. Remove transmission.
7. Remove engine rear support mounting bolts. Raise rear of engine just enough to take weight off rear support and remove crossmember.
8. Loosen exhaust pipe support bracket-to-clutch housing bolts. Loosen clamp and swing support bracket out of the way.
9. On V8 models, remove clutch housing plate.
10. On all models, remove remaining clutch housing bolts and take off clutch housing. On six-cylinder models, remove dowel bolts first.
11. Remove clutch from flywheel.

1956-58

1. Disconnect battery ground strap.
2. On Champion and Flighthawk remove oil level gauge and tube; remove starter without disconnecting cables and tie it out of the way.
3. On Commander, President, Powerhawk and Skyhawk, remove starter.
4. Remove clutch operating shaft.
5. Remove transmission.
6. Remove two bolts which hold rear support insulator cage to crossmember. Jack up rear of engine to relieve weight of engine from crossmember, and remove crossmember.
7. Loosen and swing exhaust pipe support bracket out of the way.
8. On Commander, President, Powerhawk and Skyhawk, remove clutch housing cover plate.
9. Remove remaining housing mounting bolts or cap screws and remove clutch housing. On Champion and Flighthawk, remove dowel bolts first.

1959-62

1. Disconnect battery ground cable.
2. On 6-cylinder models, remove oil level gauge and tube, remove starter mounting capscrews without disconnecting cables and tie starter out of the way.
3. On V8 models, remove starter.
4. Remove clutch operating shaft.
5. Remove transmission.
6. Remove two bolts or nuts which hold engine rear support insulator to crossmember. Raise engine with a jack under rear of oil pan just enough to relieve weight of crossmember; then remove crossmember.
7. On V8's remove clutch housing cover plate.
8. Unfasten clutch housing and lift out of car. On 6-cylinder engines, remove dowel pins first.
9. Reverse removal procedure to install the clutch and adjust free pedal travel.

TRANSMISSION, REPLACE

1955-62

1. To remove the transmission, drain the case.
2. Disconnect the U-joint from the transmission flange and remove the propeller shaft support stud nuts. Then remove the front propeller shaft and support rearward on the slip yoke splines. Move the end of the shaft to one side as far as possible and tie it in position.
3. Disconnect shift rods from transmission levers, and remove the speedometer cable from the transmission case. If overdrive equipped, disconnect wires and control cable.
4. Unfasten the transmission from the clutch housing. Remove the clutch operating shaft, bracket and bearing from the transmission case.
5. Move the transmission rearward until the clutch shaft is free of the clutch and remove the unit from the car.

Fig. 1 Exploded view of synchromesh transmission without overdrive. Typical of all Six-cylinder models. The V8 transmission is similar except that the low-reverse mainshaft gear has the shift fork groove facing the front

6. To install, reverse removal procedure.

TRANSMISSION REPAIRS

Three Speed, 1955-62

Note—The following outlines the procedure for conventional transmissions. For repairs on the overdrive unit, see the *Overdrive Chapter*.

Disassemble, Fig. 1

1. Take off cover and gasket.
2. Pull off companion flange.
3. Remove mainshaft rear bearing retainer and speedometer drive gear from mainshaft.
4. Remove main drive gear bearing retainer.
5. Remove small snap ring from main drive gear.
6. With brass drift and hammer, move countershaft rearward just enough to free up lock plate in shaft groove at rear end.
7. Make a dummy countershaft exactly the length of the countershaft and thrust washers combined. The purpose of the dummy shaft is to retain in position the needle rollers, sleeve and thrust washers when removing and installing the countershaft gear cluster.
8. Place the end of the dummy shaft against the front end of the countershaft and with a soft hammer, carefully drive the countershaft rearward out of the case, leaving the cluster gear, dummy shaft and related parts in the bottom of the case.
9. With a small brush, paint a fine line across the synchronizer rings, sleeve and second and high mainshaft gear to insure replacement of these parts in their original position.
10. To remove the main drive gear, place a brass bar or drift against the rear face of the drive gear teeth at the top (not synchronizer gear teeth) and carefully drive the gear and bearing forward out of the case.
11. With a brass bar placed against the front end of the mainshaft, drive the mainshaft rear bearing out through the rear of the case.
12. Using snap ring pliers, remove the snap ring from the front end of the mainshaft.

13. Holding the synchronizer parts and mainshaft gears together as a unit, move the mainshaft to the right and disengage the shifter fork and shoe from the grooves in the shifter sleeve and low gear. Then twist and withdraw the mainshaft through rear of case.
14. With a long brass drift, drive the reverse idler gear shaft out of the rear of the case and lift out the idler gear.
15. Lift the countershaft gear cluster and related parts straight out of the case to prevent the needle rollers from spilling. Then carefully remove the thrust washers and note the position of each to insure exact replacement.
16. With a punch, drive out the taper pins securing the shift shafts in position, upward out of the case.
17. Remove the nuts, washers and levers from the shift shafts and take shafts out of case. Also remove the interlock sleeve, detent balls, spring and pin.

Assembly Notes

Regardless of appearance, all gaskets and oil seals should be replaced. When installing oil seals, coat the outside of the seal and inside of housing with red or white lead or gasket sealer to insure leak-tight joints. Leather seals should be soaked for 24 hours before installing them.

After installing the shift shaft levers, move either one into any in-gear position and with one end of the interlock contacting a shift shaft cam, measure the clearance with a feeler gauge between the opposite end of the sleeve and the cam of the other shift shaft. This clearance should be .001″ to .007″. If not within these limits, remove the sleeve and replace with one of the proper length, available in five different lengths.

When installing the countershaft cluster gear, install the front washer with bronze face to the gear and lug at top. The rear inner (bronze) washer should be installed so the lugs will engage the slots in the cluster gear and the outer (steel) washer with the lug at top. With the countershaft installed temporarily, check the end play of the cluster gear. Do this by inserting a feeler gauge between the rear thrust washers. End play should range from .006″ to .016″. If greater than this, install new thrust washers.

With correct end play established, remove the countershaft with the dummy shaft, allowing the cluster gear and related parts to lie in the bottom of the case until after the main drive gear, mainshaft and reverse idler gears are installed. Then raise the cluster gear and install the countershaft.

3 SPEED TRANS.

1956-58 President Classic and Golden Hawk

NOTE—The following outlines the procedure for conventional transmissions. For repairs on the overdrive unit, see the *Overdrive Chapter*.

Fig. 2 Three speed transmission. 1956-58 President Classic and Golden Hawk

Disassemble, Fig. 2

1. Remove side cover and shift fork assembly from case.
2. Remove rear housing retainer screws.
3. Move housing rearward about ½″ and rotate to expose rear end of countershaft.
4. Tap countershaft rearward and remove Woodruff key in end of shaft.
5. Then, using a suitable bar which is exactly the same length as the cluster gear and thrust washers combined, drive countershaft out with this bar, allowing cluster gear (with bar in cluster) to lie in bottom of case.
6. Raise front end of mainshaft so that the synchronizer sleeve will pass over countershaft cluster gear and remove mainshaft and rear housing assembly from the case.
7. Remove mainshaft front bearing rollers from bore of main drive gear.
8. Remove main drive gear bearing retainer and gasket.
9. Remove small snap ring and washer from main drive gear.
10. Place assembly in arbor press and press main drive gear shaft out of bearing.
11. Remove large bearing snap ring and tap main drive gear bearing out of case.
12. Remove countershaft gear cluster from bottom of case, being careful not to spill the countershaft bearing rollers.
13. To remove the reverse idler gear, tap the shaft rearward out of the case and remove the gear.
14. To disassemble the mainshaft, remove the front bearing spacer from the front end of the shaft. Mark the synchronizer sleeve, gear, blocker rings, second speed gear and low and reverse sliding gear so that they can be reinstalled in their original positions. Remove the synchronizer gear snap ring. Then slip the synchronizer assembly off the shaft. Slip the second speed and low gears off the shaft.
15. To remove the mainshaft from the rear housing, remove the bearing snap ring and tap the shaft and bearing out of the housing.
16. If necessary, remove the thrust washers and bearing rollers from the countershaft gear cluster.

Assembly Notes

Reverse the foregoing procedure to assemble the transmission, being sure to observe the following:

1. The reverse idler gear should be installed with the chamfered ends of the gear teeth and the smaller diameter shoulder to the front of the case. Then after the keyway is placed in the slot, drive the reverse idler shaft in until the end of the shaft is flush with the case.
2. Assemble the bearing rollers in the cluster gear, referring to Fig. 2, and using stiff grease to hold them in place around the assembly bar mentioned in disassembly procedure.
3. When installing the countershaft gear thrust washers, the front (large) thrust washer should be placed so that the lug is up and faces the front when the assembly is installed. The rear washer should be placed against the cluster so the lugs engage the notches in the gear. Place the entire cluster gear assembly in the bottom of the case. Slip

Fig. 3 Four speed transmission. 1961-62 Hawk

the steel spacer between the case and the rear thrust washer with the tab up.

4. When installing the oil slinger on the main drive gear shaft the concave side should be toward the gear.
5. Main drive gear bearing snap rings are available in six sizes. Be sure to select one which fits snugly in the groove.
6. When installing the mainshaft in the rear housing, make sure the snap ring is in the bore of the rear housing. Then insert the shaft in the housing, tap into position and install the front snap ring.
7. When assembling the mainshaft, align the marks of the low and reverse sliding gear and the mainshaft and install gear on shaft. The gear is installed with the shift fork channel toward the front end of the shaft. Install the second speed gear with the clutch cone forward.
8. When assembling the synchronizer, place the gear on the bench with the long hub up. Insert the shifter plates in the slots of the gear. Then align the marks made at disassembly and slip the sleeve on the gear. The shift fork channel in the sleeve must be down. Install the lock springs so that the identical ends of the springs are hooked in the same shifter plate.
9. When installing the synchronizer on the mainshaft, place the rear blocker ring on the second speed gear. Align the marks of the gear and shaft and install the synchronizer on the mainshaft with the shift fork channel to the rear of the shaft.
10. Before installing the shift cover, shift one of the shafts into an in-gear position and, with one end of the interlock sleeve against the cam of the shaft, measure the clearance between the other end of the sleeve and the cam with a feeler gauge. If the clearance is not within the limits of .001″ to .007″, replace the interlock sleeve with one of sufficient length to establish the correct clearance. Sleeves are available in four different lengths.

3 SPEED GEARSHIFT, ADJUST

To adjust the steering post gearshift control, first disconnect the shift rods from the transmission shift levers, noting the position of each clevis. Check to see that the shift levers on the transmission are in neutral, which can be determined by the action of the interlock.

Remove the back-up light switch (if so equipped). Position the locating bar of the special tool made for the purpose in the opening in the steering post jacket and under the shift levers. Place the other half of the clamp in position, engaging the stud on the locating bar. Install the thumb nut and tighten to hold the levers in position.

By turning the threaded clevis, adjust the length of each shift rod so that the holes in the clevis and shift lever are in alignment. Then insert the clevis pin and secure the clevis with the lock nut. Repeat this procedure with the other shift rod. After adjusting both rods, remove the gauge and check the operation of the gearshift control.

FOUR SPEED TRANS.

1961-62 Hawk

1. To disassemble, side cover, Fig. 3.
2. Remove front bearing retainer.
3. Drive lock pin from bottom side of reverse shifter lever boss and pull shifter out about ⅛″. This disengages reverse shift fork from reverse gear.
4. Unfasten case extension from rear bearing retainer (5 bolts). Tap extension to rear. When reverse idler shaft is out as far as it will go, move extension to left so reverse fork clears reverse gear and remove extension.

Fig. 4 Four speed transmission gearshift linkage. 1961-62 Hawk

5. Remove snap ring from end of mainshaft. Remove speedometer gear, reverse idler gear, tanged thrust washer and reverse gear.
6. Remove self-locking bolt attaching rear bearing retainer to case. Then remove mainshaft assembly.
7. Lift front reverse idler gear and thrust washer from case.
8. Remove pilot rollers from main drive gear and 4th speed synchronizing ring.
9. Remove main drive gear snap ring and spacer washer. Tap drive gear from front bearing. From inside case, tap out front bearing and snap ring.
10. From front of case, tap out countershaft and remove countershaft gear and thrust washers.
11. Strip mainshaft of all parts.

Assemble

Mainshaft

1. From rear of mainshaft, assemble 1st-2nd clutch to mainshaft with sleeve taper toward rear and hub to front. Press 1st gear bushing on shaft.
2. Install 1st gear synchronizing ring so notches in ring correspond to keys in hub.
3. Install 1st gear with hub to front, and thrust washer. Make sure that grooves in washer are facing 1st gear.
4. Press rear bearing with snap ring groove toward front, making certain bearing is firmly seated against shoulder on mainshaft.
5. Choose correct selective fit snap ring and install it in mainshaft groove behind rear bearing. Snap rings are available in three thicknesses; using ring that will produce from zero to .005″ clearance between rear face of bearing and front face of snap ring.
6. From front of mainshaft, install 2nd gear synchronizing ring so notches in ring correspond to keys in hub. Install 2nd speed gear with hub toward rear, and install 2nd-3rd gear thrust (bearing) washer.
7. Install 3rd gear with hub to front and 3rd gear synchronizing ring with notches to front.
8. Install 3rd-4th gear clutch (hub and sliding sleeve) with taper toward front, making sure that keys in hub correspond to notches in 3rd gear synchronizing ring. Install snap ring in mainshaft groove in front of clutch.
9. Install rear bearing retainer plate. Spread snap ring on plate to allow it to drop around rear bearing and press on end of mainshaft until snap ring engages groove in rear bearing.
10. Install reverse gear with shift collar to align.
12. Press speedometer gear on mainshaft so it is 4½″ from center of gear to flat surface of rear bearing retainer. Install snap ring in groove at rear of mainshaft.

Fig. 5 Linkage gauge block for adjusting four speed transmission

Countershaft Gear

1. Install spacer in countergear.
2. Using grease to retain rollers, install 20 rollers in each end of gear, two .050″ spacers, 20 more rollers, then one .050″ spacer. Insert dummy shaft to hold parts in place during installation.

Transmission, Assemble

1. Place countershaft tanged thrust washers in place, retaining them with grease and being sure that tangs are resting in notches in case. Set counter gear in bottom of case.
2. Press bearing onto main drive gear with snap ring groove to front and firmly seat bearing against shoulder of main drive gear.
3. Install spacer washer and selective fit snap ring in groove on gear stem. Use ring that will provide zero to .005″ clearance between rear face of snap ring and front face of spacer washer.
4. Install main drive gear through side cover opening. Place snap ring in groove in front bearing.
5. With transmission resting on its front face, move countergear into mesh with main drive gear, being sure thrust washers are in place. Install key in end of countershaft and, from front of case, tap shaft until its end is flush with rear of case and dummy shaft is displaced. End play of countergear should be not more than .025″.
6. Install 14 pilot rollers in main drive gear pocket, using grease to hold them in place.
7. Place a greased gasket on front face of rear bearing retainer.
8. Install 4th gear synchronizing ring on main drive gear with clutch key notches toward rear.
9. Position reverse idler gear thrust washer (untanged) on machined face of ear cast in case for reverse idler shaft. Position front reverse idler gear on top of thrust washer with hub facing rear of case.
10. Lower mainshaft assembly into case, making certain that notches on 4th gear synchronizing ring correspond to keys in clutch assembly.
11. Install self-locking bolt attaching rear bearing retainer to case, tightening it to 20-30 ft. lbs.
12. From rear of case, insert rear reverse idler gear, engaging splines with portion of gear within case.
13. Place greased gasket on rear face of rear bearing retainer.
14. Install remaining tanged thrust washer on reverse idler shaft, being sure tang is in notch in idler thrust face of extension case.
15. Place two clutches in neutral.
16. Full reverse shifter shaft to left side of extension and rotate shaft to bring reverse shift fork to extreme forward position in extension. Line up forward and rear reverse idler gears, being sure front thrust washer is in place.
17. Start extension into transmission case by carefully inserting reverse idler shaft through reverse idler gears. Slowly push it on shifter shaft until shift fork engages reverse gear shift collar. When fork engages, rotate shifter shaft to move reverse gear rearward, permitting extension to slide onto case.
18. Install 3 extension-to-case bolts, tightening to 35-45 ft. lbs., and 2 extension-to-retainer bolts, tightening to 20-30 ft. lbs. Use suitable sealer on lower right attaching bolt (viewed from rear).

19. Adjust reverse shifter shaft so that groove in shaft lines up with hole in boss and drive in lock pin from top of boss.
20. Install main drive gear bearing retainer and gasket, making certain oil well lines up with oil outlet hole. Install bolts with suitable sealer and tighten to 15-20 ft. lbs.
21. Install a shift fork in each clutch sleeve. With both clutches in neutral, install side cover and gasket. Tighten cover bolts evenly to 10-20 ft. lbs. torque. Use suitable sealer when installing lower right bolt. Install shift levers.

Gearshift, Adjust

As shown in Fig. 5, a simple gauge block, locally made to the specifications indicated, will aid in making the proper adjustments. The adjustments can be made without the gauge block by having an assistant hold the manual shift lever in neutral position.

1. Referring to Figs. 4 and 5, remove move gearshift lever seal from floor pan.
2. Place transmission in neutral and, if gauge block is used, position in slot.
3. Remove clevis pin at each shift lever.
4. On each shift rod, adjust threaded clevis to permit free entry of pin into hole in transmission shift lever.
5. Connect clevises to levers.
6. Remove gauge block and check shifts. If any roughness exists, one of the clevises may require adjustment of about ½ turn. Determine the rod and clevis requiring adjustment by sighting along the slot where the gauge block was used. *If transmission is removed from car, shift linkage should be adjusted before transmission is reinstalled.*

B-W AUTOMATIC DRIVE

The operation, construction and repair procedures on this transmission are given in detail in the *Borg-Warner Automatic Drive* chapter in this manual. The following gives the service adjustments for the various models.

Hand Control Linkage, 1955 All Models

1. Disconnect the hand control bell crank-to-transmission rod. Then check the length of the rod, using the gauge shown in Fig. 6. The tool is made to gauge a distance of $7\frac{5}{16}''$ (marked 9G and 17A) on one edge, and a distance of $7\frac{5}{8}''$ (marked 10G and H) on the other edge. The edge marked 10G and H is also used for 1953-56 models. Adjust the rod according to the tool.
2. Then, on 1952 models shorten the rod by one full turn of the ball joint end.
3. On 1953-56 models, measure the diagonal distance from the center of the cotter pin hole at the bell crank end to the center of the ball at the ball joint end as shown in Figs. 7 and 8 and adjust the rod to the dimension shown for the model being serviced.
4. After the rod is correctly adjusted and lock nut tightened, set the transmission selector valve lever in Reverse, Fig. 9, and shift the hand control lever to the R position.
5. Adjust the length of the hand control tube-to-bell crank rod by turning the clevis until the holes in the clevis and bell crank line up so that the cotter pin will slip in easily. Then tighten the lock nut and remove the clevis pin.
6. Shift the hand control lever to the P position and set the transmission selector lever to the Parking position (all the way forward). In this position the propeller shaft should be locked.
7. Check the adjustment of the hand control tube-to-transmission rod by slipping the clevis pin into the assembled clevis and bell crank. If the pin does not slip in easily, change the adjustment of the rod by ½ turn to give a compromise fit for both P and R positions. If ½ turn does not give the proper adjustment, check the entire linkage for wear, looseness, binding or distortion.
8. Connect the rod to the bell crank and check the operation of the transmission.

Fig. 6 Special gauge for checking length of hand control bell crank-to-transmission rod. Gauge is marked on either end for the various models

Fig. 7 Correct measurement of bell crank-to-transmission rod on 1955-57 two-door, four-door and Land Cruiser models

Fig. 8 Correct measurement of bell crank-to-transmission rod on 1955-57 Hardtop convertibles and five-passenger coupe models

Throttle Control Linkage, 1955-56 Champion

1. Adjust engine idle speed to 500-550 rpm by means of the idle adjustment screw at the carburetor throttle lever.
2. Remove the wire from the anti-creep switch and remove switch, Fig. 10.
3. Measure the distance between the accelerator cross shaft bracket and the contact plate. This measurement should be ¼" with the accelerator fully released. If it is not, remove the clevis pin from the accelerator cross shaft-to-bell crank rod clevis, loosen the lock nut and adjust the clevis until the ¼" measurement is obtained.
4. Then install the anti-creep switch until the plunger of the switch just contacts the contact plate.
5. Install the wire, turn on the ignition and adjust the release switch as required until an audible click is heard in the solenoid. Then tighten the lock nut.
6. Shift the selector lever to the Park position. With the Accelerator-to-Transmission Control Adjusting Tool, Fig. 10, at its maximum length, hook one end of the tool in the notch of the accelerator cross shaft lever and the other end at the upper right rear corner of the battery box, as shown. In doing so, the accelerator push rod will be pulled forward, causing the bell crank-to-carburetor throttle rod to partially open the carburetor throttle. Adjust the length of the tool by turning the turnbuckle until the accelerator is brought forward far enough to put the throttle valve in its wide open position.
7. Disconnect the accelerator cross shaft-to-transmission rod ball joint from the governor control lever.
8. Turn the governor control lever forward (clockwise) until the resistance of the detent is felt (see Fig. 11).
9. Adjust the length of the rod by turn-

Fig. 9 Transmission selector valve lever shown in Reverse position

ing the ball joint until it can be slipped easily into the governor control lever when the lever is at the point where the resistance of the detent is felt (full throttle position).

10. Remove the accelerator-to-transmission control adjusting tool.
11. Check the linkage operation as follows: (a) With floor mat properly in place and accelerator fully depressed, remove ball joint and check to make sure the governor control lever on the transmission is at the end of its forward travel. (b) With the accelerator fully released, check to make sure there is at least ¼" of free travel of the governor control lever before spring pressure is felt as it is turned forward. If the adjustment is correct, connect the ball joint to the governor control lever. (c) If full forward travel or the proper amount of free travel of the governor control lever are not obtained, recheck the linkage adjustment. If proper travel is still not obtained, check for and eliminate any bind, distortion or interference in the linkage which would affect proper adjustment.

Fig. 10 Transmission control linkage. 1955-56 Champion

Throttle Control Linkage, 1955 V8

1. To adjust, first disconnect the anti-creep release switch wire at the switch. Remove the switch from the bell crank bracket. Leave all three springs attached.
2. With the selector lever in the P or N position, adjust the engine idle speed to 500-550 rpm by means of the idle adjusting screw. Make sure the screw is contacting the lowest step of the fast idle cam. Make sure the throttle return check is functioning properly.
3. Place the idle speed adjusting screw on the 4th step of the fast idle cam (lowest step being the first step). Adjust the throttle check screw until it just contacts the pad on the throttle shaft lever.
4. Loosen the two threaded rod lock nuts. The throttle actuating spring turns and secure with the lock nut. will sag sligthly. Hold the cross shaft arm against the bracket and at the same time tighten the forward nut on the threaded rod until the spring is taut. The idle adjusting screw will just start to break contact with the low step of the fast idle cam. Back off the forward threaded rod nut just enough to let the idle adjusting screw lightly contact the low step of the fast idle cam.
5. Install the anti-creep release switch in the cross shaft bracket. Turn it in until the idle adjusting screw starts to break contact with the low step of the fast idle cam. Back off the anti-creep switch three complete
6. Back off the forward threaded rod nut three complete turns. This will allow approximately ⅛ to $\frac{3}{16}$" sag in the throttle actuating spring. Tighten the rear threaded rod nut.
7. A piece of ½" or ¾" angle iron 15¼" long can be used to hold the accelerator in a position to hold the throttle valve in its wide-open position. Pull the hand brake control handle out about four or five inches. Position the angle iron between the hand brake plunger, just forward of the handle, and the accelerator pedal. Depress the accelerator pedal nearly to the wide-open position and at the same time slide the lower end of the angle iron up near the top of the accelerator pedal. Then slowly push the hand brake in until the carburetor throttle valve is just to its wide-open throttle position. This is the point where any further movement of the accelerator pedal would only result in operating the over-travel spring. The angle iron will now hold the linkage in this position while the accelerator cross shaft-to-governor linkage is adjusted.

Governor Control Linkage, 1955 All Models

The throttle control linkage must be adjusted before this adjustment is attempted.

1. Disconnect accelerator rod ball joint from the governor lever. *Note whether it is removed from the inner or outer hole if the governor lever has two holes.*
2. Turn the governor control lever forward (clockwise), Fig. 11, until the resistance of the detent is felt and check the adjustment of the rod. If the linkage is correctly adjusted, the stud of the ball joint can easily be slipped into the proper hole of the governor lever. If adjustment is required, loosen the ball joint lock nut and turn the ball joint until the stud is aligned with the proper hole in the lever. Make sure that the lever is still at the point where the resistance of the detent is felt. After making the adjustment, tighten the lock nut securely. *Do not install the ball joint nut at this time.*
3. Remove the angle iron from the accelerator push rod. Then check linkage operation as follows:
4. With the floor mat properly in place and accelerator *fully* depressed, slip the ball joint stud out of the governor lever and check to make sure the governor lever is at the end of its forward travel.
5. With the accelerator fully released, check to make sure there is at least ¼" of free travel of the governor lever before spring pressure is felt as it is turned forward. If the adjustment is correct, install and tighten the ball joint stud nut.
6. If full forward travel or the correct amount of free travel of the governor lever is not obtained, recheck the linkage adjustment. If proper travel is still not obtained, check for and eliminate any bind, distortion or interference in the linkage. A possible point of interference could be between the bell crank-to-transmission rod and the car floor pan. Remove the front splash pan from the frame side rail and check for this condition. If the condition exists, bend the floor pan (not the linkage) out of the way. Also check all linkage mounting bolts for tightness.

Fig. 11 Governor control lever 1953-55

Fig. 12 Transmission mounted on special lift ready for installation. 1953-57

Automatic Transmission (Only), Replace

1. Drain fluid from transmission and converter.
2. On 1955-56 Coupe and Hardtop models, remove body front pillar support crossmember.
3. Remove complete propeller shaft assembly.
4. Disconnect hand control bell crank-to-transmission rod from selector control shaft lever.
5. Disconnect accelerator cross shaft-to-transmission rod ball joint from governor control lever.
6. Remove speedometer cable.
7. On 1955 models, disconnect anti-creep wires from switch and unfasten wiring harness from transmission.
8. Remove two lower transmission case-to-converter housing stud nuts.
9. Place transmission lift, if available, Fig. 12, under transmission.
10. Remove two upper attaching screws and install pilot studs in the screw holes.
11. Slide transmission out of converter housing. If oil transfer tube does not come out with transmission, remove it from converter.
12. If converter is to be removed, remove pilot studs from converter housing.
13. Reverse the removal procedure to install the transmission, using the Spline Alignment Fixture, Fig. 12, on transmission shaft. Also install the alignment fixture in the torque converter as shown in Fig. 13. When installation is completed, check and adjust the control linkage.

Torque Converter, Replace

1. Remove starter motor.
2. Remove transmission.
3. Disconnect exhaust pipes and muffler as required to provide additional clearance and working space.
4. The engine rear support crossmember must be removed. But before doing so, the engine weight must be lifted off the crossmember. The jack used to lift the engine should not bear against the bottom of the oil pan but rather on the oil pan flanges. A suitable support should be made capable of supporting 600 lbs. The support may be made of wood or channel iron in a U shape so that the weight is taken on the oil pan flanges.
5. Place the engine support saddle 3″ to 5″ forward of the engine rear plate and up against the oil pan flange. Then install the jack on the support.
6. Remove rear engine support stud nuts and raise engine just enough to have separation between support and crossmember, and remove crossmember.
7. Remove converter housing front plate, and converter housing from dowels.
8. To facilitate removal of converter housing, lower engine, being careful not to pull off water outlet hose. If additional clearance is required, drain cooling system and disconnect outlet hose.
9. Remove torque converter.
10. Reverse removal procedure to install the converter, using the Converter Aligning Flange, Fig. 14, in the bore of the converter housing and over the pump drive fingers on the converter. Hold flange in place with two transmission attaching screws. Rotate converter through two complete revolutions to center the converter.

Starter Cut-Out Switch

The starter cut-out switch is located at the base of the steering post jacket and acts to break the starter solenoid circuit when the selector lever is in the D, L or R position and also to control the operation of the back-up light if so equipped.

Removal—Remove the two screws holding the switch to the steering post jacket. Lift out the switch and disconnect the hand control-to-switch rod. Disconnect the wiring cable from the switch.

Fig. 13 Spline alignment fixture inserted in torque converter. 1953-57

Fig. 14 Converter aligning flange tool being installed on converter. 1953-57

Installation—Align the pin hole in the switch lever with the corresponding hole in the switch body. Install a pin through the holes that maintain alignment of the lever and body. Connect the wiring cable to the switch. Assemble the rod to the switch.

With the selector lever in N position, place the switch in position on the steering post jacket and install the screws. Remove the pin from the switch lever and body and test the operation of the switch.

Idle Adjusting Screw Switch

The idle adjusting screw switch is located on the carburetor throttle lever and acts to release the anti-creep system when the accelerator pedal is depressed to move the car. It replaces the usual idle adjusting screw and the position of the switch determines engine idling speed.

Removal—Disconnect the wire leading to the idle adjusting screw switch. Screw the switch out of the carburetor throttle lever.

Installation—With the lock spring in position on the switch, screw the switch into place in the carburetor throttle lever. Start the engine and, with the selector lever in the N position, set the engine idle at 500-550 rpm by turning the switch in or out as required. Connect the lead-in wire to the switch, and check anti-creep operation.

Anti-Creep Solenoid Control Switch

This switch is located at the rear of the transmission case and acts to prevent operation of the anti-creep system while the car is moving forward. The anti-creep system is not used on 1956 models so the pressure switch is replaced by a ¼″ pipe plug. However, if anti-creep system is desired, a kit is available for installation on these models.

Fig. 15 Flightomatic throttle linkage. 1956-60 six-cylinder models

Fig. 16 Flightomatic throttle linkage. V8's

Removal—Disconnect the two control cables from the switch. Unscrew the switch from the rear of the transmission case.

Installation—Screw the switch into the back of the transmission case. Connect the control cables to the switch and check its operation.

Anti-Creep Solenoid Valve

The anti-creep solenoid valve is fastened to the rear of the brake master cylinder and acts to hold pressure on the rear brakes after the brakes have been applied to stop the car with the accelerator fully released.

Removal—With the ignition off, disconnect the cables at the connectors. Disconnect the brake tube from the solenoid valve to the adapter and take off the valve.

Installation—Insert the solenoid valve into the adapter and fasten the valve in place with the attaching screw. Connect the brake tube to the solenoid valve outlet. Bleed the brake system. Connect the control cables. Check operation of valve as follows:

With rear wheels stationary, ignition on and accelerator fully released, depress the brake pedal firmly and release. Rear wheel brakes should now be set, preventing the rear wheels from turning. The rear wheel brakes should release when the ignition is turned off or the accelerator is depressed.

FLIGHTOMATIC TRANSMISSION

A detailed service procedure on this transmission may be found in the *Automatic Transmission Section* of this Manual. The following covers the removal of the transmission and converter, and linkage adjustments.

Throttle Linkage, 1958-60 Six

1. Set selector lever in P or N position and operate engine until automatic choke is in wide open position.
2. Disconnect rod which connects accelerator bracket, Fig. 15, to auxiliary bellcrank.
3. Connect tachometer to engine and set engine idle speed to 550 rpm.
4. Disconnect rod which connects main bellcrank to auxiliary bellcrank.
5. Adjust the screw to provide 5/16" gap between bellcrank and pad as shown. A 5/16" drill may be used as a gauge.
6. Adjust ball joint on the main bellcrank-to-auxiliary bellcrank rod until ball joint stud freely enters hole in main bellcrank lever. During this adjustment the carburetor idle speed screw must be against its stop and the 5/16" gap must be maintained.
7. Disconnect and adjust length of main bellcrank-to-throttle valve outer lever rod, Fig. 16, so that the ball joint stud freely enters throttle valve outer lever. During this adjustment, the throttle valve must be held against its internal stop (outer lever held to rear of transmission).
8. Remove ball joint stud from throttle valve outer lever and shorten rod four complete turns of the ball joint assembly.
9. Reinstall stud and tighten nut securely.

Fig. 17 Flightomatic throttle linkage at transmission. All 1956-61

10. Hold accelerator bracket arm approximately 3⅞" from the firewall and adjust accelerator bracket-to-auxiliary bellcrank rod clevis until clevis pin freely enters clevis and bracket arm.

1959-60 Lark 6 Service Note

It is essential that the trottle control rod from bellcrank to carburetor be properly adjusted. The correct adjustment provides for a dimension of 11 1/16" between the centerline of the cotter pin hole and the centerline of the ball stud. After the rod has been adjusted to this length, it should not be changed in any subsequent adjustment operation.

1958-62 V8's

1. Set selector lever in P or N position and operate engine until the automatic choke is in wide open position.
2. Make sure throttle return check (dashpot) is operating correctly.
3. Connect tachometer to engine and set idle speed to 550 rpm.
4. Set stop on bellcrank to provide 17/64" gap between bellcrank pads, Fig. 16. A 17/64" drill may be used as a gauge.

1961-62 Six

1. On right side of engine, Fig. 18, disconnect adjustable rod from manifold bellcrank.
2. With engine idling at 550 rpm in N or P, and with crossover bellcrank against bellcrank stop plate, adjust length of adjustable rod so end of rod slides freely in hole in manifold bellcrank.
3. On the left side of the engine, Fig. 19, adjust length of adjustable rod to provide ⅜" clearance between rib of floor pan and accelerator pedal bellcrank arm.

Manual Control Valve Linkage

1. Disconnect shift lever-to-transmission manual valve lever rod, Fig. 17, at the ball joint.
2. Place selector lever in D position,

Fig. 18 Throttle linkage at right side of engine. 1961-62 six

Fig. 19 Throttle linkage at left side of engine. 1961-62 Six

which is the center of the manual valve lever travel.

3. Adjust shift lever-to-manual valve lever rod until the ball joint stud will slip freely through the hole in the manual valve lever.

Transmission, Replace

1. Drain oil from transmission and converter.
2. On Coupe and Hardtop models, remove body front pillar support crossmember.
3. On cars equipped with dual exhaust system, remove left exhaust system.
4. Remove complete propeller shaft assembly.
5. Disconnect rods from transmission levers.
6. Remove speedometer cable.
7. Support the transmission on a suitable lift. Then unfasten the transmission from the converter and remove from converter housing.
8. Installation is made in the reverse order of removal.

Converter, Replace

1. Remove the transmission and starting motor.
2. Disconnect rear exhaust pipe from front exhaust pipe and pull muffler and pipe assembly rearward.
3. The rear engine support crossmember must be removed to permit removal of the converter housing. But before removing the crossmember, the engine weight must be lifted off the crossmember. The jack used to lift the engine should not bear against the bottom of the oil pan; the engine should be supported at the oil pan flanges. A suitable support should be made capable of supporting 600 lbs. The support may be made of wood or channel iron in a U shape so that the weight is taken on the oil pan flanges.
4. Remove the rear engine stud nuts and raise the engine just enough to have separation between insulators and crossmember.
5. Remove crossmember.
6. Remove converter bell housing. To facilitate removal, lower rear of engine, being careful not to pull off the water outlet hose. If additional clearance is necessary, drain cooling system and remove this hose.
7. Unfasten and remove converter from the drive plate.
8. To install, reverse removal procedure.

Rear Axle and Brake Section

Refer To Hydraulic Brakes Chapter For Brake Adjustments

REAR AXLE, REPLACE

1. Remove axle nuts.
2. Raise car and support on two stands placed under frame directly in front of rear springs.
3. Remove rear wheels.
4. Pull off hubs and drums.
5. Disconnect brake pipes at wheel cylinders.
6. Remove bolts from backing plates.
7. Remove brake pipe from axle housing.
8. Remove backing plates and adjusting shims and suspend them from frame.
9. Disconnect propeller shaft at axle housing and move to one side.
10. Remove spring U bolts from axle housing and disconnect shock absorbers from spring plates. On models so equipped, disconnect stabilizer shaft from spring plates.
11. Move axle assembly from under car.
12. Reverse removal procedure to install and, after connecting brake pipes, bleed the brake system.

REAR AXLE REPAIRS

In this unit, Fig. 1, the drive pinion is held in position by shoulders in the differential carrier upon which the pinion bearing cups seat. The pinion position is maintained by shims located between the rear bearing and the rear shoulder in the differential carrier. Shims between the bearing spacer and the front bearing cone are used to adjust pinion bearings.

The shimmed type of differential bearing adjustment is employed, Fig. 2. The procedure for making this adjustment, as well as the assembly of the differential case, replacing the ring gear, checking ring gear and pinion backlash, and other differential case operations, is given in the *Rear Axle Chapter*.

The axle tubes are pressed into the differential carrier to form a one-piece housing. To overhaul the unit, therefore, the rear axle assembly must be removed from the chassis.

Pinion & Bearings, Replace

After removing the axle shafts and differential unit, unscrew the pinion flange retaining nut and pull off the flange. The pinion may then be removed from the carrier by driving it out of the front bearing with a brass drift and

hammer. After the pinion is free of the front bearing, pull it out through the rear of the carrier.

Mount the pinion in a press and press the pinion shaft out of the bearing. When replacing the bearing, select a suitable sleeve or length of pipe of the same diameter as the cone so the rollers or cage will not be damaged when being forced on the shaft.

Drive the front bearing cup and oil seal out of the forward end of the carrier. If the rear bearing cup is to be replaced or if the pinion setting is to be changed, remove the rear bearing cup.

To change the pinion setting, the shims behind the rear bearing cup should be measured with a micrometer. The necessary shims may then be removed or added to obtain the proper pinion setting as indicated when a pinion setting gauge is used (see *Rear Axle Chapter*). After the required shims have been added or subtracted, replace the rear bearing cup.

When making a pinion adjustment, the same thickness of pinion bearing adjusting shims should be added or removed at the rear bearing cup to retain the proper pinion bearing adjustment.

To install the pinion, support it under the head with a wood block while the pinion flange is reinstalled. The pinion oil seal should not be replaced until after the pinion setting has been checked.

Pinion Bearings, Adjust

The only occasion for adjusting the drive pinion bearings is when a new pinion or differential carrier is installed. To make the adjustment, install sufficient shims between the bearing spacer and front bearing so that when the pinion retaining nut is tightened against the pinion flange, all rollers in the bearing are tight, but still permit rotating the pinion by hand.

Pinion, Adjust

After adjusting the pinion bearings, the position of the pinion may be checked.

Fig. 2 Ring gear and pinion backlash adjustments. All models

Fig. 1 Rear Axle. 1955-62

If a pinion setting gauge is available, check the pinion depth as outlined in the *Rear Axle Chapter*. If a correction is necessary, disassemble the pinion and, if it is to be moved toward the center of the axle, add shims between the rear bearing and rear shoulder in the carrier. If the pinion has to be moved away from the center of the axle, remove shims from this point.

If no pinion setting gauge is available, assemble the differential unit in the carrier and check the tooth contact by painting the ring gear teeth as described in the *Rear Axle Chapter*. After satisfactory tooth contact has been established, remove the pinion flange to make the installation of the oil seal. Using a compressing collar and the pinion flange retaining nut, press the new oil seal in place. Install the pinion flange, tighten the nut solidly in place and lock it with a new cotter pin.

AXLE SHAFTS

To remove an axle shaft, jack up the wheel and pull off the hub and brake drum. Block the brake pedal in such a manner that it cannot be depressed. Disconnect the hydraulic brake line from the wheel cylinder. Remove the mounting screws and take off the outer oil seal, shims and brake support. The shaft and bearing may then be pulled out of the housing. The inner oil seal may be removed at this time.

Replace the shaft and bearings in the reverse order. If the old parts are replaced and the shims have not been disturbed, the end play should be correct when the parts are assembled. However, if a new axle shaft, bearing, differential carrier or housing has been installed, it will be necessary to check the end play.

Axle shaft end play can be checked when all parts have been replaced except the wheel and hub. To make the check, rap each axle shaft after the nuts are tight to be sure the bearing cups are seated. Then mount a dial indicator on the axle housing with its contact button touching the end of the shaft. Work the shaft in and out by hand and note the reading on the indicator. If an adjustment is necessary, remove the oil seal and brake support and add or remove shims as required to bring the end play within the limits shown in *Rear Axle and Brake* chart.

When making this adjustment, an equal thickness of shims should be removed or added on each side of the axle housing to maintain the central position of the axle shafts.

BRAKE MASTER CYLINDER, REPLACE

To remove the unit, unhook the brake pedal pullback spring, and also clutch pedal pullback spring if connected to master cylinder support strap. Disconnect fluid line or lines at master cylinder. Disconnect brake pedal-to-master cylinder rod at brake pedal. Unfasten master cylinder from its mounting and remove from car.

To install, reverse removal procedure and bleed the brake system.

POWER BRAKE UNIT, REPLACE

To remove the unit, disconnect manifold vacuum supply hose at the power unit. Disconnect stop light switch wires and hydraulic lines. Unfasten the unit from its mounting and remove from car.

If necessary, repairs to the power unit may be accomplished in the manner described in the *Power Brakes Chapter*. To install the unit, reverse the removal procedure and bleed the system as outlined in the *Power Brakes Chapter*.

Front End and Steering Section

CASTER & CAMBER, ADJUST

Caster and camber adjustments are both made at the upper control arm outer pin. To adjust caster, loosen the lock bolt. Remove the grease fitting from the rear bushing and insert an Allen wrench into the opening provided in the pin. A full turn of the pin will change caster ½ degree. After the correct adjustment is obtained, install the grease fitting and tighten the pinch bolt.

To adjust camber, turn the upper control arm outer pin with an Allen wrench in the same manner as for caster adjustment. One half turn of the pin covers the entire range of camber adjustment. Adjusting camber will make only a slight change in the caster adjustment but recheck the caster to make sure it is within specifications.

TOE-IN, ADJUST

Turn the left tie rod to bring the wheel in the straight-ahead position. Then adjust toe-in by turning the right tie rod. Be sure to tighten tie rod clamps securely.

FRONT END REPAIRS

Lower Control Arm Removal

1. Raise car and support it with stationary jacks under frame.
2. Remove wheel assembly.
3. Disconnect front stabilizer shaft from lower control arm and remove rubber rebound bumper.
4. Remove shock absorber, Fig. 1.
5. Inner end of lower control arm is then disconnected to allow removal of front spring and spring pads, Fig. 2.
6. Remove threaded bushings from outer end of lower control arm.
7. Using a suitable drift, remove pin which locks lower control arm outer pin to steering knuckle support.
8. Drive out outer pin with brass drift to permit removal of lower control arm and grease seals.
9. Place lower control arm in vise and remove inner shaft threaded bushings.
10. Shift inner shaft to one side as far as possible.
11. Move opposite end of shaft outward and remove shaft and grease seals from control arm.

Lower Control Arm Install

1. Place control arm in vise.
2. Install seals on inner shaft.
3. Insert one end of inner shaft in one member of control arm, push in as far as possible, swing opposite end into position and insert it in other member of arm.
4. It is necessary to spread ends of control arm .015″ to prevent bind at threaded bushings. Install Spreader Tool, Fig. 3, and tighten threaded tip of tool finger tight, then turn one-half turn more to spread ends .015″.
5. With spreader in position, place inner shaft in center between ends of control arm, being sure control arm does not bind on shaft.
6. It is also necessary to spread outer ends of lower control arm .015″. Determine outer dimension by adjusting a pair of calipers, Fig. 4, so setting includes a .015″ feeler gauge which is inserted between outside edge of control arm and one prong of calipers.
7. After setting calipers, position outer end of lower control arm at lower steering knuckle support and install outer pin, with a seal on each side of steering knuckle support.
8. Using a screwdriver in slot provided in end of outer pin, turn pin and align slot at center of outer pin and hole of knuckle support and install lock pin.
9. Then install Spreader Tool, Fig. 4, between inner surfaces of outer ends and spread ends until outside dimension is equal to setting of calipers.
10. Centralize outer end of control arm on outer pin.
11. Install bushings and tighten them securely. Then remove spreader tool, and make sure control arm turns freely on outer pin.
12. Install front spring and spring pads and complete installation of control arm.
13. On 1955-58, install shock absorber.
14. Connect stabilizer shaft, install rebound bumper and wheel assembly.

Upper Control Arm Removal

1. Raise car and support it at outer end of lower control arm.
2. Remove front wheel.
3. On 1950 Commander, disconnect

Fig. 1 Front suspension. 1955-62

Fig. 2 Lower control arm disconnected to allow removal of front spring

shock absorber arm from frame bracket.

4. Remove pinch bolt which holds upper control arm in head of kingpin.
5. Remove threaded bushings and outer pin and grease seals.
6. Mark top front of control arm inner shaft so that position of shaft can be noted after assembly is removed.
7. Remove bolts and nuts which hold inner shaft to frame bracket and remove upper control arm.

Caution — Note position of inner shaft as identified by the mark which was made during removal of arm. The holes in the inner shaft are drilled off the centerline of the shaft and turning the shaft over will increase or decrease the camber slightly less than ¾ degree. Therefore, on assembly, it is important that the shaft be installed in the original position.

Upper Control Arm Repair & Install

1. Place upper control arm in vise.
2. Remove shock absorber and grease seal from 1950 Commander control arm.
3. Remove bushings from inner shaft.
4. Shift shaft as far as possible to one side, move opposite end of shaft out of control arm end and remove shaft and seals from arm.
5. Remove grease seals from shaft.
6. To assemble, install seals on inner shaft.

Fig. 3 Using spreader tool to keep lower control arm members aligned to prevent binding of threaded bushings

7. Insert one end of shaft into control arm, bring opposite end in position and insert in control arm.
8. It is necessary to spread inner ends of upper control arm .015″. Using calipers and .015″ feeler gauge, determine outside dimension of control arm.
9. Then with Spreader Tool, Fig. 5, spread inner ends of control arm until outside dimension is equal to setting of calipers.
10. With spreader tool in place, centralize inner shaft with ends of control arm and install bushings. Make sure shaft is free.
11. The outer end of the upper control arm must also be spread .015″.
12. Using calipers and .015″ feeler gauge, determine outside dimension.
13. Position upper control arm at kingpin and insert outer pin, with hex opening in pin toward front through one of control arm ends.
14. Install grease seal on pin, push pin through end of kingpin and install other grease seal.
15. Center outer pin in kingpin by aligning groove of outer pin with hole in kingpin and install pinch bolt.
16. Install Spreader Tool and spread ends of control arm to setting of calipers, Fig. 6.
17. Center end of kingpin in control arm and, with spreader still in place, install bushings.
18. On 1950 Commander, install shock absorber and cork grease seal on control arm.
19. With marked side of inner shaft up, align holes of inner shaft and holes of frame bracket and install retaining bolts.
20. On 1950 Commander, connect shock absorber arm link to frame bracket.
21. Install wheel.
22. Check and adjust camber and caster as outlined previously.

Steering Knuckle Service

1. Raise car and support it at outer end of lower control arm.
2. Remove front wheel assembly.
3. Remove brake plate from knuckle flange without disturbing brake hose and suspend brake assembly in an out of the way position. Do not allow assembly to hang on hose.
4. Disconnect tie rod from knuckle arm.
5. Remove kingpin retaining nut. Then use a lead mallet to drive kingpin upward out of lower support.
6. Lift upper control arm and kingpin assembly and swing kingpin outward.
7. Remove Woodruff key from kingpin, then remove steering knuckle, shim and thrust bearing.
8. Remove cork gasket from lower end of knuckle.

To service the knuckle, proceed as follows:

1. First remove needle bearing at lower end of knuckle.
2. Insert removal adapter in knuckle and place it on upper surface of bearing.
3. Place knuckle in arbor press. Then, using the bushing of the knuckle as a pilot, insert arbor and press bearing out of knuckle.

Fig. 4 Using calipers and spreader tool to establish proper spread of outer ends of lower control arm

4. To remove bushing, invert steering knuckle, insert removal adapter and place it on inner end of bushing.
5. Insert pilot in bearing end of knuckle and, using the arbor, press bushing out of knuckle.
6. To remove kingpin, remove bushings and outer pin as outlined under Upper Control Arm.
7. If necessary to replace the steering knuckle arm, remove arm retaining nut and, using a suitable drift, drive the arm out of the knuckle and remove the Woodruff key from the arm.

Assembly Notes

Assemble the steering knuckle in the reverse order. However, when pressing the bearing into the steering knuckle, be sure that the pressure is applied to the lettered end of the bearing. Then, to determine the steering knuckle end play on the kingpin, first place the kingpin in a vise and place the steering knuckle on the kingpin without the cork gasket which is normally installed on the bottom of the knuckle. Place the thrust bearing and shims on the kingpin. Insert a .003″ to .006″ feeler gauge between the shoulder of the kingpin and steering knuckle. Place a straightedge or small scale across the top surface of the thrust bearing and lower shoulder of the kingpin and press down on the thrust bearing. If the surface of the

Fig. 5 Using spreader tool to keep upper control arm inner ends aligned to prevent binding of bushings

thrust bearing is not flush with the shoulder of the kingpin, remove or add shims as required. After proper end play is obtained, remove the knuckle, thrust bearing and shims from the kingpin. Then reassemble the parts in the reverse order of their removal.

HORN SOUNDER & STEERING WHEEL

1962

1. Remove horn button by carefully prying the ornamental plastic insert out of center of horn ring and remove horn ring and attaching parts.
2. Use a suitable puller to remove steering wheel.
3. Disconnect button cable at button switch.

1959-61

1. Remove cap from steering wheel by inserting a knife blade under the button and forcing it out.
2. Remove retaining screws and take out horn ring and insulators.
3. Remove steering wheel retaining nut and lock plate.
4. Use puller to remove wheel.

1955-58

1. On models without horn ring, remove horn button by pushing down on button and turning it 1/3 turn. On models with horn ring, follow procedure outlined for 1959 models.
2. Remove wheel nut and use puller to remove wheel.

STEERING GEAR, REPLACE

1955-58

1. Disconnect battery and horn switch wire at connector.
2. On V8 models, disconnect battery cable at starter switch.
3. On V8 Coupe and Hardtop models, remove battery and battery box.
4. Remove steering gear housing, steering post jacket and steering wheel as an assembly.
5. On V8 Coupe and Hardtop models, remove left front engine support cushion and raise this corner of engine about 2".
6. Pull off pitman arm.
7. Unfasten steering gear from frame and take it out through hole in dash and into car. Wrap a cloth around the gear housing top cover to prevent spilling lubricant during removal.
8. To install, reverse removal procedure.

1959-62

1. Remove battery.
2. Disconnect horn switch wire at connector.
3. Disconnect battery cable at starter switch.
4. Remove battery box on Sport Coupe.
5. Remove steering column jacket.
6. On V8's (except Sport Coupe) remove left front engine support cushion stud nut and raise engine about 1½". *Before raising engine, remove distributor cap.*
7. Remove reach rod from pitman arm.
8. Unfasten steering gear from frame and roll gear over so that it is upside down. Then lift and remove it through engine compartment.

Fig. 7 Ross cam and twin lever steering gear. A gear with a single cam lever is used on 1957-60 V8 models

ROSS STEERING GEAR

This type steering gear, Fig. 7, can be identified by the location of the filler hole plug which is at the upper end of the housing.

Two adjustments are provided for the steering gear assembly: steering post end play and cam lever shaft stud clearance. Before making adjustments, free the steering gear of all load by disconnecting the steering gear from the steering linkage.

Fig. 6 Using calipers and spreader tool to establish proper spread of outer ends of upper control arm

Steering Post End Play

Loosen the cam lever shaft adjusting screw lock nut, Fig. 8, and back off the adjusting screw. Using a spring scale that is calibrated in ounces, measure the amount of pull required to turn the steering wheel. The scale should be hooked to a tag wire or string which is wrapped around the rim of the steering wheel at the spoke. A steady pull of 4 to 7 ounces should turn the steering wheel smoothly. If the pull is not within limits, loosen the steering post jacket clamp, remove the top cover cap screws and add or remove shims as required to secure the proper scale reading, Fig. 9.

Cam Lever Shaft Stud Clearance

With the steering post end play adjusted correctly, locate the center of travel (high spot) of the steering gear.

Fig. 8 Adjusting cam lever stud clearance. Ross steering gear

While turning the steering wheel back and forth over the high spot, turn the lever shaft adjusting screw, Fig. 8. Keep the lock nut snug until a slight drag is felt. Then tighten the lock nut.

To check the adjustment, hook the spring scale to the steering wheel rim and check the amount of effort required to turn the wheel in either direction through the high spot. The scale reading should be 16 to 24 ounces.

Steering Gear Repairs

If repairs are required on the steering post or its bearings, remove the steering gear assembly from the car as outlined previously. But if only the cam lever shaft requires service, it may be removed from the gear housing without removing the entire steering gear from the car.

SAGINAW STEERING GEAR

1955-60

This steering gear may be identified by the location of the filler hole plug which is on a boss located near the center of the housing. It can also be identified by the large lock nut at the lower end of the housing, Fig. 10.

There are two adjustments for the steering gear assembly: worm shaft end play, and the clearance adjustment between the worm shaft and roller. Although there are but two adjustments, the complete procedure outlined below must be followed. Before making adjustments, free the steering gear of all load by disconnecting the steering gear from the steering linkage.

Fig. 9 Removing shim to eliminate steering post end play. Ross steering gear

Worm Shaft Bearings

Loosen the lock nut, Fig. 11, and turn the adjusting screw a few turns in a counterclockwise direction. This releases the worm shaft bearings from the load caused by the close meshing of the worm and roller. Turn the steering wheel gently in one direction until stopped by the gear, then back away one turn.

Attach a spring scale to the rim of the steering wheel and measure the pull required to turn the wheel. The spring scale reading should be between 6 and 10 ounces. If not within these limits, loosen the lock nut and turn the bearing adjuster, Fig. 10, as required to bring it within limits (clockwise to increase drag; counterclockwise to decrease it). Tighten lock nut and recheck the adjustment.

Tighten the jacket bracket-to-instrument panel bolts and recheck the worm shaft end play adjustment to make sure a bind is not imposed on the gear. If the scale readings are not now within specified limits, it will be necessary to loosen the gear housing mounting bolts and slightly shift or shim the assembly to correct the binding condition.

Worm Shaft & Roller Clearance

After proper adjustment of the worm shaft end play is obtained, adjust the roller-to-worm clearance. First turn the steering wheel gently through the entire range of travel, carefully counting the total number of turns. Then turn the wheel back exactly halfway, to the center position.

Turn the adjusting screw, Fig. 11, clockwise to take out all the lash and tighten lock nut. Then check the pull at the wheel as in the first adjustment. Take the highest reading on the scale as the wheel is pulled through the center position. This should be 14 to 30 ounces. After setting the lock nut, recheck the adjustment.

Steering Gear Repairs

If repairs are required on the worm shaft and bearings, the steering gear assembly will have to be removed from the car. But if only the cross shaft assembly requires service it may be removed from the gear housing without removing the entire steering gear from the car.

STEERING GEAR REPAIRS, 1961-62

Disassemble

1. Rotate steering worm until nut is in center of travel, Fig. 12.
2. Remove sector shaft nut.
3. Remove side cover and sector shaft from housing.

Fig. 10 Worm shaft end play adjustment. Saginaw steering gear. 1955-60

4. Turn adjuster screw in end of sector shaft down through cover.
5. Remove end cover with worm bearing, outer race and thrust washer.
6. To remove lower worm bearing, outer race and thrust washer from cover, loosen worm bearing adjuster screw lock nut and turn screw in though cover.
7. Grasp lower end of steering worm and draw steering shaft and nut assembly out of steering housing. *Be sure too keep shaft in horizontal position so that nut does not move against stops at any time, thereby causing damage to ball return mechanism. Disassembly of worm nut is not recommended.*

Assemble

1. Install steering shaft and nut assembly in steering housing, keeping ball nut away from stops on worm.
2. Install worm bearing adjusting screw with lower worm bearing, outer race, and thrust washer in end cover.
3. Install end cover and attaching parts on gear housing, making sure bearings seat properly.
4. Tighten worm bearing adjusting screw until a slight drag is felt on bearings. Do not tighten lock nut.
5. Install pitman arm.
6. Install sector shaft and adjuster screw inside cover.
7. Rotate steering column until ball

28. Nut

Fig. 12 Saginaw recirculating ball nut type steering gear. 1961-62

nut is in center of travel so that center tooth on sector shaft will enter center space on nut.

8. Install side cover and sector shaft in gear housing.
9. Tighten sector shaft adjusting screw until a slight drag is felt on bearing but do not tighten lock nut.
10. After steering gear has been installed in car, adjust gear as outlined below.

Steering Gear, Adjust

The recirculating ball type steering gear has two adjustments: the worm bearing adjustment and cross shaft end play adjustment.

Worm Bearing Adjustment—Disconnect steering connecting rod at pitman arm. Turn steering wheel to either right- or left-hand stop. Then check load to pull steering wheel back to a point not less than 90° from the straight-ahead position of the steering wheel. The load should be between 2¼ to 6¾ inch pounds. Load is checked with a spring scale hooked to the rim of the steering wheel. To adjust, loosen lock nut and turn the worm bearing adjusting screw as required. Tighten the lock nut and recheck the adjustment.

Cross Shaft End Play—Turn the steering wheel about 90° each way through center. The pull through center should be between 8 and 9 inch pounds. If an adjustment is required, loosen the lock nut and turn the cross shaft adjusting screw in the direction required to obtain the desired result. Tighten the lock nut when the adjustment is correct and recheck the adjustment.

POWER STEERING, REPLACE

1955-58

1. Disconnect and remove battery.
2. On C and K models, remove battery box.
3. Unfasten and slip steering post collar up out of the way.
4. If equipped with automatic transmission, disconnect quadrant light and starter cut-out switch cables.
5. If equipped with turn signals, disconnect cables.
6. Disconnect shift lever rod or rods.
7. Loosen jacket clamp bolt at lower end of jacket.
8. Remove steering wheel.
9. Unfasten and slip steering jacket off steering post.
10. Separate steering coupling, keeping collector ring and insulators intact, and remove steering post assembly. Tape coupling studs to prevent damaging threads when removing the unit.
11. On W, F and D Commander and President Sedan models, remove left rocker arm cover.
12. Disconnect reach rod from pitman arm.
13. Remove pitman arm pinch bolt.
14. Move fender gravel deflector out of the way and remove steering gear-to-mounting bracket bolts.
15. On W, F and D Commander and President Sedan models, it may be necessary to shift the unit against the fender apron to gain clearance to remove the pitman arm. Then remove pitman arm.
16. Disconnect flexible hoses from pump. Tape openings of pump fittings and hoses or install suitable plugs.
17. Shift unit rearward, inserting its top end through opening in firewall. Lift lower end of unit, turning it as necessary to gain clearance past fender apron and battery box on W, F, D and Y models. Then lift unit from car.
18. To install, reverse removal procedure. Then after connecting the hoses, fill gear housing to the proper level and bleed system as outlined in the *Power Steering Chapter*.

1959-62

1. Remove battery.
2. Remove steering post collar screws and slip collar up out of the way.
3. Remove horn wire brush terminal and bracket.
4. If equipped with automatic transmission, disconnect guadrant light and starter cutout switch cables.
5. If equipped, disconnect turn signal cables.
6. Disconnect shift lever rod or rods.
7. Loosen jacket clamp bolt at lower end of jacket.
8. Remove steering wheel.
9. Remove column jacket spring.
10. Loosen column jacket-to-instrument panel bracket clamp screw and remove screws and shims (if present). Then slip jacket off steering post.
11. Remove four steering post coupling nuts, separate coupling (keeping insulators intact) and remove post assembly.
12. Remove left rocker arm cover.
13. Disconnect reach rod from pitman arm.
14. Remove pitman arm pinch bolt.
15. Move fender gravel deflector out of the way and remove three steering gear housing-to-frame bolts. *It may be necessary to shift the unit against the fender apron to gain clearance when removing pitman arm*
16. Disconnect hoses from pump.
17. Shift power steering unit rearward, inserting its top end through opening in firewall. Then lift lower end as necessary to gain clearance past fender apron and lift out of car.

Instruments and Windshield Wiper

INSTRUMENT CLUSTER

1955

1. Disconnect battery ground cable.
2. Remove right lower panel cover (4 screws).
3. Disconnect oil pressure pipe at gauge and remove the two stud nuts and clamps.
4. Pull instrument group forward out of panel. Tag and disconnect cables.
5. The individual instruments can then be removed from the base plate after removing base plate screws.

All 1956-58 and 1959-62 Hawks

1. The instruments are mounted in individual cases and are retained by brackets or covers and stud nuts.
2. Disconnect battery ground cable.
3. Remove cables, pipes and lamps as necessary.
4. Remove stud nuts and pull instrument forward out of panel.

1959-62 Larks

The instruments are mounted in a cluster and are retained in the panel by means of brackets and nuts. If it is necessary to replace either the fuel or temperature gauge remove the case unit and disassemble.

To remove the case unit, disconnect battery ground cable. Remove gauge wires, nuts and brackets. The speedometer is removed in the same manner.

WINDSHIELD WIPER

1955-62

To remove the wiper motor, it will be necessary to remove the radio (if equipped). Then unfasten the wires or hose and linkage from the motor and unfasten the motor from the cowl panel.

1961-62 Models with Cowl Air Intake

1. Disconnect battery.
2. Remove cowl air intake grille and screen.
3. Disconnect wires and linkage from motor and remove motor.

①—Incorrect toe-out, when other adjustments are correct, generally indicates bent steering arms.

②—Incorrect kingpin or knuckle support angle with correct camber indicates bent suspension arms or knuckle support.

Engine Section

ENGINE MARKINGS

Current production engines are marked with a letter following the serial number when the engine is not strictly standard.

The letter "A" means crankshaft journals are .010″ undersize.

The letter "B" means the bores are .010″ oversize.

The letter "C" means .010″ oversize bores and .010″ undersize crankshaft journals.

ENGINE, REPLACE

Jeeps

1. Disconnect one battery cable.
2. Drain cooling system.
3. Remove radiator stay bar on CJ-3B.
4. Remove radiator and heater hoses.
5. Remove fan and fan hub.
6. Remove radiator and shroud.
7. Disconnect fuel line at pump.
8. Disconnect windshield wiper hoses.
9. Remove air cleaner and two breather hoses.
10. Disconnect choke and throttle controls.
11. Remove starting motor.
12. Disconnect generator wires.
13. Disconnect primary wire at coil.
14. Disconnect heat indicator and oil pressure gauge tubes.
15. Disconnect exhaust pipe from manifold.
16. Remove front engine supports. This will allow engine to drop slightly and will permit access to the two top bolts on the bell housing.
17. Install a suitable lifting sling on engine. Attach sling to hoist and take up slack.
18. Pull engine forward or roll vehicle backward until clutch clears bell housing, and lift engine from vehicle.
19. To install, reverse procedure.

Four-Cylinder Station Wagons

1. Disconnect one battery cable.
2. Drain cooling system.
3. Remove hood and radiator brace rods.
4. Remove heater and radiator hoses.
5. Remove radiator.
6. Disconnect fuel line at pump.
7. Disconnect windshield wiper hose.
8. Remove carburetor air cleaner.
9. Disconnect throttle controls.
10. Remove starting motor.
11. Disconnect generator wires.
12. Disconnect primary wire at coil.
13. If equipped with overdrive, disconnect overdrive control wires. (To avoid possibility of error when connecting overdrive wires, mark or tag them.)
14. Disconnect heat indicator and oil gauge wires.
15. Disconnect exhaust pipe from manifold.
16. Remove engine support bolts.
17. Unfasten bell housing from engine.
18. Install a suitable lifting sling on engine. Raise engine high enough to relieve weight from front engine supports and pull engine forward, or roll vehicle backward, until clutch clears bell housing. Then remove engine from vehicle.
19. To install, reverse procedure.

F-Head 6-Cyl. Station Wagons

1. Remove hood and radiator stay bar.
2. Drain cooling system.
3. Disconnect one battery cable.
4. Remove air cleaner.
5. Disconnect wires from temperature sender, coil primary and secondary at distributor, starter solenoid, generator, oil sender.
6. Remove coil.

Six cylinder 148" and 161" L-Head Engine

Fig. 2 Six cylinder head tightening. 1955 L-Head

Fig. 3 Six-cylinder F-head engine head tightening

Fig. 4 Cylinder head tightening sequence. 226" engine

Fig. 5 Cylinder head tightening. Four-cylinder F-head engines

7. Disconnect heater hoses at engine.
8. Disconnect throttle link and remove choke control from carburetor.
9. Disconnect accelerator pedal link from throttle bell crank and push back into vehicle.
10. Disconnect fuel line at pump.
11. Disconnect windshield wiper hose from vacuum booster tube.
12. Remove radiator and hoses.
13. Remove exhaust pipe from manifold.
14. Remove bolts from engine front supports.
15. Disconnect ground strap at left front engine support.
16. Remove bell housing-to-rear engine plate bolts and remove battery ground strap from bell housing if so attached.
17. The engine is now free of connections and can be lifted from vehicle.
18. To install, reverse procedure.

"6-226" Station Wagons

1. Drain cooling system.
2. Remove hood and radiator stay bars.
3. Remove radiator hoses and heater hoses.
4. Remove radiator and shroud.
5. Disconnect battery ground cable.
6. Disconnect wires from temperature sender, oil pressure sender, starter, generator, coil and secondary at distributor.
7. Remove air cleaner.
8. Disconnect accelerator pedal linkage from bell crank.
9. Disconnect vacuum line from wiper motor.
10. Disconnect fuel line from pump.
11. Disconnect engine ground strap from front engine support.
12. Disconnect clutch linkage.
13. Disconnect exhaust pipe at manifold.
14. Disconnect front engine supports.
15. The engine is now free of connections and can be lifted from vehicle.
16. To install, reverse foregoing procedure.

CYLINDER HEAD

Before the cylinder head is installed, make certain that all dirt and carbon is removed from both the head and block. File or hone all high spots.

Use a torque wrench when tightening down cylinder heads. Uneven or excessive tightening of nuts may distort cylinder bores, causing compression loss and excessive oil consumption.

Tighten cylinder heads in the sequence

Fig. 6 Position of valve stem guides in six cylinder 148" and 161" L-Head engines

Fig. 7 Position of valve stem guides in four cylinder L-Head engine

F-Head four cylinder engine

F-Head four cylinder engine

shown in Figs. 2 to 5, tightening them a little at a time in the proper order a couple of times around before final tightening to the torque values given in the *Engine Tightening Chart*. After the engine has warmed up to operating temperature, recheck the torque and tighten as required.

On F-Head engines, be sure to check intake valve operating clearances after the final tightening.

Note—Tightening cylinder heads on F-head engines without removing rocker arms may be accomplished with a wrench having an $\frac{11}{16}''$ box on one end and a $\frac{1}{2}''$ square box on the other end. This, together with a torque wrench will do the job.

Fig. 8 Position of valve guides in F-head engines

Service Note

Accurate alignment of the cylinder head, gasket and block on L6-226 engines is required to prevent gasket failure. Two cylinder head bolt holes, at opposite corners of the head (positions 24 and 26 in Fig. 4) have a slightly smaller diameter than the other holes and can be used for guide pins.

The guide pins can be made by cutting the heads off two cylinder head bolts. Cut slots in the end from which the heads were removed to install and then remove the guide pins.

The torquing sequence for the head bolts is shown in Fig. 4.

ROCKER ARMS

F-Head Engines

To remove the rocker arm assembly, proceed as follows:

1. Remove carburetor air cleaner.
2. Disconnect spark plug wires.
3. Drain cooling system.
4. Remove rocker arm cover.
5. Remove rocker arm bracket screws and lift off rocker arm assembly.

Before disassembly, mark rocker arms, brackets and shaft so they can be reassembled in the original positions.

VALVES, ADJUST

L-Head Engines

The valves may be adjusted when the engine is at normal room temperature. Crank the engine over until the valve to be adjusted is fully closed. Hold the lifter body with a tappet wrench to prevent it from turning. Then turn the tappet adjusting screw until the proper clearance is obtained. Measure the clearance with a feeler gauge and, after adjusting one tappet, proceed in like manner with the others, being certain that the valve being adjusted is fully closed.

In addition to the conventional method of adjusting tappets by locating the distributor rotor and then adjusting the tappets by following the firing order of the engine, the following method may also be used:

Four-Cylinder Engines

Valves Fully Raised	Adjust Tappets
1 and 3	6 and 8
2 and 5	4 and 7
6 and 8	1 and 3
4 and 7	2 and 5

Six-Cylinder 148" & 161" Engines

Valves Fully Raised	Adjust Tappets
1 and 3	10 and 12
7 and 9	4 and 6
2 and 5	8 and 11
10 and 12	1 and 3
4 and 6	7 and 9
8 and 11	2 and 5

Six-Cylinder 226" Engine

Valves Fully Raised	Adjust Tappets
1 and 3	10 and 12
8 and 9	4 and 5
2 and 6	7 and 11
10 and 12	1 and 3
4 and 5	8 and 9
7 and 11	2 and 6

F-Head Engines

The exhaust valves (in block) may be adjusted in the same manner as outlined for L-head engines. However, the intake valves may best be adjusted with the engine running after it has warmed up to operating temperature.

If the cylinder head has been tightened, be sure to recheck intake valve clearances and adjust as required.

VALVES, REMOVE

L-Head Engines

After removing the cylinder head, take off the valve chamber covers and use cloth to block off the holes in the valve chamber to prevent the valve locks from falling into the crankcase.

With a suitable valve spring compressor, raise the springs on those valves which are closed and remove the valve locks. Then turn the crankshaft until those valves which are open are closed and remove the remaining valve locks.

Remove all valves and place them in a board with numbered holes so they can be identified as to the valve port from which they were removed.

F-Head Engines

Follow the same procedure in removing the exhaust valves from these engines as outlined for L-head engines.

In removing the intake valves from the head a suitable fixture is available which holds the valves closed and compresses the spring at the same time.

Fig. 5A Checking valve spring installed height

Six-cylinder F-Head engine

Six-cylinder F-Head engine

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 5A. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

VALVE SPRING TESTING

After taking out the valves, remove the springs and wash them with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check valve spring pressure on a spring testing fixture if one is available. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications given in the *Valve Data* chart within 10 per cent should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded.

VALVE GUIDES

After the valves and springs have been removed, clean the valve guides with a wire brush, and clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads, as well as the gum which might have accumulated on the stems.

Check the clearance between the valve stems and guides carefully. The standard clearances are given in the *Valve Data* chart.

Excessive clearance between the valve stem and guide will cause improper seating and burned valves. When there is too much clearance between intake valve stems and guides, there is a tendency to draw oil vapor through the guide on the suction stroke, causing excessive oil consumption, fouled spark plugs and poor low speed performance.

Fig. 9 Layout of valve system. Four cylinder L-head engine. This is typical of the F-head engine except that the intake valve mechanism is contained in the cylinder head

To check valve stem-to-guide clearance, take a new valve and place it in each valve guide and feel the clearance by moving the valve stem back and forth. If this check shows excessive clearance, it will be necessary to replace the valve guide. If the clearance is not excessive when checking with a new valve but is excessive when checked with the old valve, the old valve stem is worn and a new valve must be installed.

If it is necessary to replace the valve guides, the old guides can be driven out with a special driver which is available for the purpose. However, in lieu of the driver, the guides can be pulled out by using a suitable piece of pipe together with a long bolt and suitable washers.

When replacing the guides, maximum engine performance can only be secured when the guides are installed correctly (see Figs. 6, 7 and 8).

VALVES, GRIND

In refacing valves, take off the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced.

Inspect the valve seats in the block and head for cracks, burns, pitting, ridges or improper angle. During any general engine overhaul it is advisable to reface the valve seats regardless of their condition. If new valve guides are required, they must be installed before refacing the seats if the equipment used has a valve guide pilot.

The valve seat width after refacing should measure not more than $\frac{5}{64}$ in. The width may be checked by placing a scale across the face of the seat.

A simple check can be made to prove the fit of the valve in the valve seat by spreading a thin film of Prussian Blue on the valve face and then inserting the valve into the valve seat. With hand pressure, rotate the valve ¼ turn and then remove it and observe the transfer of Prussian Blue to the valve seat. An uneven transfer of Prussian Blue will indicate an inaccurate valve and valve seat refacing operation.

VALVE LIFTERS

These lifters are of the mushroom type operating in guide holes cast in the block. This means that the camshaft will have to be removed from the engine if valve lifters require replacement.

Whenever the camshaft is removed, inspect the faces of the lifters where they contact the cams and replace any that are scored, rough or cracked. Check the clearance of the lifters in the guides, replacing those that have worn excessively. Oversize available is .004 in. and the guides must be reamed to accommodate them.

CAMSHAFT & GEAR COVER, REPLACE

All Engines (Except 6-226)

1. Drain cooling system.
2. Remove radiator and grille or guard.
3. Remove cylinder head, valves and springs.
4. On L-head engines, remove manifolds.
5. Remove fuel and oil pumps.
6. Remove oil pan.
7. Remove crankshaft pulley (and vibration damper on 6-cyl.).
8. Remove fan assembly.
9. On CJ-2A and CJ-3A, remove nuts from front engine support.
10. Remove engine front cover.
11. Remove camshaft gear and thrust plate.
12. Tie valve lifters up to their highest point of travel with string wrapped around the adjusting screws and

Fig. 10 Valve timing. Six-cyl. 226" engine

attach to manifold studs. Spring clip type clothespins or small "C" clamps may also be used.

13. On CJ-2A and CJ-3A, raise front of engine until camshaft will clear front crossmember.
14. Remove camshaft from engine.
15. To install, reverse foregoing procedure and set valve timing as shown in Fig. 10.

"6-226" Engines

1. Drain cooling system.
2. Remove radiator.
3. Remove vibration damper.
4. Remove timing chain cover.
5. Remove timing gears and chain.
6. Remove fuel pump.
7. Remove cylinder head.
8. Remove oil pan and oil pump.
9. Remove valves and springs.
10. Hold valve lifters up with spring type clothespins or string to prevent them from interfering with camshaft as it is being withdrawn.
11. Unfasten camshaft thrust plate from cylinder block and withdraw the camshaft.
12. To install, reverse removal procedure and set valve timing as shown in Fig. 11.

Fig. 11 Valve timing for timing gear driven engines

Fig. 12 Layout of crankshaft and related parts. Four cylinder engine

TIMING CHAIN

"6-226" Engines

For correct valve timing on this engine, install the chain so there are 10 pins between the sprocket timing marks, Fig. 10.

TIMING GEARS

All Except "6-226"

The camshaft is driven by a steel gear on the crankshaft and a fibre gear on the camshaft. Lubrication is positive through a jet pressed into the crankcase directly back of the contact point of the gears. When the gears are removed, check both the jet and oil passage to make sure they are clear.

When it becomes necessary to replace the timing gears, due attention must be given to the end play of both shafts and running clearance of the gears.

End play of the crankshaft is controlled by the running clearance between the crankshaft gear and gear thrust plate, Fig. 11. The end play is adjusted by shims placed between the thrust plate and the end of the front main bearing. Shims .002 in. thick are available for this adjustment. When the thrust plate or washer is removed, be sure it is reinstalled with the beveled inner edge toward the crankcase.

End play of the camshaft is determined by the running clearance between the camshaft gear and thrust plate. The standard clearance is .003 to .0055 in. which is determined by the thickness of the camshaft gear thrust plate spacer, Fig. 9. Should a check indicate not enough clearance, place a thin shim between the thrust plate spacer and the shoulder on the camshaft. Clearance may be reduced by dressing off the spacer slightly. Whenever the spacer is installed, make sure that the beveled inner edge is toward the rear.

End play of both the camshaft and crankshaft can best be measured with a dial indicator.

Standard running clearance between the gears is .000 to .002 in., which should be checked with a dial indicator.

To set the valve timing, install the crankshaft gear followed by the camshaft gear with the camshaft positioned to allow installation with the timing gear marks meshed, Fig. 11.

PISTONS & RODS, REMOVE

After removing the cylinder head and oil pan, examine the cylinder bores above the ring travel area. If the bores are worn so that a shoulder or ridge exists at this point, remove the ridge with a ridge reamer to avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod caps and push pistons and rods out of cylinders, using care to prevent rod bolts from contacting and nicking crankshaft journals.

Make sure the rods and pistons are properly numbered so they can be reinstalled in original locations. It is advisable to install caps on rods to avoid mixing parts.

PISTONS & RODS, ASSEMBLE

All Except "6-226" Engine

As shown in Fig. 13, pistons should be assembled to the connecting rods so that the oil spray hole in the rod *faces* away from the camshaft side of the engine with the vertical slot in the piston facing the camshaft side.

"6-226" Engine

When correctly assembled, the oil spray hole in the rod *faces* the camshaft side of the engine with the vertical slot in the piston facing away from the camshaft side.

PISTONS

Standard size service pistons are high limit or maximum diameter; therefore, they can usually be used with a slight amount of honing to correct slight scoring or excessive clearances in engines having relatively low mileages. Service pistons are also furnished in .005, .010, .015, .020 and .030 in. oversizes.

Before a honing or boring operation is started, measure all new pistons with a micrometer at points exactly 90 degrees away from the piston pin. Then select the smallest piston for the first fitting. The slight variation usually found between pistons in a set may provide for correction in case the first piston is fitted too free.

It is very important that refinished cylinder bores are trued up to have not more than .0005 in. out-of-round or taper. Each bore must be final honed to remove all stone or cutter marks and provide a smooth surface. During final honing, each piston must be fitted individually to the bore in which it will be installed and should be marked to insure correct installation.

After final honing and before the piston is checked for fit, each bore must be thoroughly washed to remove all traces of abrasive and then dried thoroughly. The dry bore should then be brushed clean with a power-driven fibre brush.

Both the piston and cylinder block must be at the same temperature (room temperature of 70 degrees) when the piston is checked for fit in the cylinder bore. Therefore the cylinder should be allowed to cool after boring or honing and before the piston fit is checked. This is important because a difference of 10 degrees between the temperature of parts is sufficient to produce a variation of .0005 in.

To check the fit of pistons, use a feeler ribbon gauge ¾ in. wide and the thickness listed in the *Piston & Ring Data* chart. Insert the piston upside down in the cylinder bore with rings removed. Locate the feeler 90 degrees from the piston pin hole, between the thrust face of the piston and cylinder wall. Hook the feeler to a spring scale. If the force required to pull the feeler out of the cylinder with the scale is as specified in the chart, the piston fit is correct. If too tight, the cylinder must be honed out until the proper clearance is obtained.

PISTON RINGS

When new piston rings are to be installed without reboring cylinders, the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glazebuster" or with a hone equipped with the finest grade of stones.

New piston rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

Fig. 13 Assemble pistons and rods as shown. All except "6-226" engine. On. "6-226" the oil spray hole faces the camshaft side with the vertical piston slot away from the camshaft side

If the piston grooves have worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

See the *Piston & Ring Data* chart for ring groove clearances and end gap clearances.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in the bore by tapping with either end of the piston, then measure the gap with feeler gauges. If necessary to increase the gap, file the ends with a smooth file.

PISTON PINS

On "6-226" engine the pins are of the full-floating type, being retained by snap rings which fit in grooves cut into the piston bosses.

On engines other than the "6-226", the pins are locked in the rods and are fitted with a clearance of .0001 to .0005 in. which is equivalent to a light thumb push fit with the parts at normal room temperature. No oversize pin is available as it is impossible to ream the connecting rod satisfactorily due to the clamp slot, and also because the piston plating should not be removed from the piston pin bore.

ROD BEARINGS

Insert type bearings consist of two half shells, the upper shell having an oil spray hole which communicates with the oil hole in the rod.

When the shells are placed in the rod and cap the ends extend slightly beyond the parting faces so that when the rod bolts are tightened the shells will be clamped tightly in place to insure positive seating and to prevent turning. *The ends of the shells must never be filed flush with the parting faces of the rod and cap.*

If this type bearing becomes noisy or is worn so that clearance on the crankpin is excessive, a new bearing of proper size must be selected and installed since no provision is made for adjustment. Under no circumstances should the rod or cap be filed to adjust bearing clearance.

Service bearings are furnished in standard sizes and several undersizes, including undersizes for reground crankshafts.

The clearances of connecting rod (and main) bearings may be checked with Plastigage which is available at any auto parts jobber and full instructions for its use are furnished with the envelope in which it is contained.

Lacking Plastigage, however, clearance may be checked with a .002 in. test shim, ¾ in. square. Place the shim between the bearing and shaft journal. Install the cap, tightening the nuts to the recommended torque. A locked bearing or drag when the rod is moved endwise on the crankshaft indicates the clearance is correct providing the rod moves endwise freely without the test shim installed. Do not overlook removing the shim.

The connecting rod nuts are locked with stamped nuts which should not be used when once removed. Install the new nuts with the flat face toward the connecting rod nut. Turn the locking nut finger tight and then tighten it only a half-turn more.

MAIN BEARINGS

When necessary to remove the crankshaft the engine will have to be removed from the chassis. And since the main bearings on all four-cylinder engines are held in place by dowels, the engine will have to be removed when their replacement becomes necessary.

Main bearings on six-cylinder engines may be removed and installed without removing the engine.

The bearings are made to size and do not require line reaming or adjustment.

When it is necessary to install new bearing shells it is advisable to measure the shaft journals with a micrometer for being out-of-round. If an out-of-round condition exists in excess of the standard running clearance of the bearings (either main or rod) a satisfactory bearing replacement cannot be made and it will be necessary to replace or regrind the crankshaft. Undersize bearings of .010 and .020 in. are available.

Before installing the shaft and bearings, use a rifle brush to clean the oil passages thoroughly in both the shaft and crankcase. If possible, blow out the holes with compressed air. Be sure the journals are not nicked or scored and that all parts are thoroughly clean.

After installing the bearings, check the running clearance to be sure it is standard (see *Engine Bearing Data* chart). Use Plastigage or a .002 in. test shim about one inch square. Place the shim between the shaft and bearing and tighten the bearing cap nuts to the recommended torque. The shaft should be locked if the clearance is at the low limit or show a drag if at the high limit when turned, proving that the clearance is correct. Do not overlook removing the test shim.

CRANKSHAFT OIL SEAL

The rear main bearing is sealed against external leakage by a lip type neoprene seal with a metal core. The seal has the advantage of being able to be slipped into place without removing the crankshaft.

For easy installation, give the seal a coat of grease. Be careful not to coat the ends of the seal as they have sealing compound applied to them.

OIL PAN

The floating oil intake is attached to the crankcase with two cap screws. Whenever the oil pan is removed, the float, screen and tube should be cleaned thoroughly in a suitable cleaning fluid to remove any accumulation of dirt. If the screen has been crushed, it is better to replace it rather than attempt to make a repair.

OIL PUMP

All Except "6-226" Engines

The oil pump is located externally on the left side of the engine. When necessary to remove the pump, first take off the distributor cap and note the position of the rotor so that the pump may be reinstalled without disturbing the ignition timing.

To install the pump without disturbing the timing, the pump gear must be correctly meshed with the camshaft driving gear to allow engagement of the driving key on the distributor shaft in the pump shaft driving slot without moving the distributor rotor. Assembly can be made only in one position because the slot and driving key are machined off center.

To disassemble the pump, Fig. 14, remove the cover and gasket. Hold a hand over the cover opening and, with the pump upside down, turn the shaft until the outer rotor slips out. Drive out the pin securing the drive gear to the shaft. Press the shaft out of the gear and slide the shaft and inner rotor out of the body.

Fig. 14 Rotor type oil pump. All except "6-226" engine

Failure of the pump to operate at full efficiency may usually be traced to excessive end play in the rotor or excessive clearance between the rotors. The clearance between the outer rotor and pump body should also be checked.

End play of the rotors is controlled by the thickness of the cover gasket which is made of special material which can only be slightly compressed. Never use other than a standard factory gasket.

"6-226" Engines

The oil pump is of the positive gear type, located at the bottom of the vertical shaft which also drives the distributor.

To disassemble the oil pump, take off the screen float. Drive out the pin which secures the drive gear to the shaft and take off the gear. Remove pump cover and gasket. Position the pump with the drive shaft end up and allow the gears to drop from the pump body. Do not remove the idler gear shaft unless worn or damaged.

Assemble the pump with new parts, using a new gasket. When replacing the upper drive gear, position it on the shaft and use a feeler gauge to measure clearance between gear and end of pump body, allowing a clearance of .002 to .004". When proper clearance has been obtained, drill a $\frac{3}{16}$" pin hole through the drive shaft, install the pin and peen it securely.

RADIATOR, REMOVE

Raise the hood, disconnect the upper and lower hose, unfasten the core from its mounting and lift it off.

WATER PUMP, REPLACE

Remove the fan belt and blades, unfasten the pump from the cylinder block and lift it off. On some models, it may be necessary to loosen the radiator core and pull it forward in order to remove the water pump assembly.

WATER PUMP REPAIRS

To disassemble the pump, take out the bearing retaining wire and press the shaft through the impeller and pump body. Remove the seal washer and seal. Place the pump shaft and fan pulley on the press in such a position that the bearing will clear the opening and press the shaft from the pulley.

To reassemble the pump, install the long end of the shaft in the pump body from the front end until the outer end of the bearing is flush with the front end of the pump body.

Dip the seal and seal washer in brake fluid and install in the impeller. Place the impeller on the bed of the press and press the long end of the shaft into the impeller until the end of the shaft is flush with the impeller.

Support the assembly on the impeller end of the shaft and press the fan pulley on the shaft so that the end of the shaft is flush with the face of the fan pulley. Move the shaft in the body so that the grooves in the bearing and pump body line up, then lock in position with the bearing retaining wire.

DISTRIBUTOR, REPLACE

All Except "6-226" Engines

The distributor is mounted on the right side of the engine and is operated by a coupling on the oil pump shaft which is driven by a spiral gear on the camshaft.

1. Remove wires from the distributor cap, noting the order in which they are assembled to assure correct reassembly.
2. Remove primary lead from terminal post at side of distributor.
3. Disconnect vacuum tube.
4. Remove distributor cap.
5. Note position of rotor in relation to the distributor housing. Mark housing to facilitate installing and timing.
6. Remove screw holding distributor to crankcase and lift unit from engine.
7. Reinstall in the reverse order of removal and set the timing as outlined below.

"6-226" Engines

To remove the distributor, disconnect the vacuum tube and low tension wire

and remove distributor cap. Remove bolt and washer that holds advance arm to adapter and lift out distributor. Install the distributor in the reverse order of removal and set the ignition timing as outlined below.

IGNITION TIMING

Crank engine to bring No. 1 piston up on its compression stroke and stop when the timing mark is in the center of the hole in the flywheel housing or when the pointer on the timing gear cover lines up with the specified timing mark on the crankshaft pulley or vibration damper (see *Tune Up Chart).* Loosen the distributor body clamp and rotate the distributor until the points close. Then turn it in the opposite direction until the points just begin to open and tighten the clamp bolt. Check the timing with a timing light.

When using a timing light, *it is advisable to disconnect the distributor vacuum line before checking timing,* otherwise the timing may be affected due to the fact that the centrifugal advance may operate if the engine is idling too fast, thus obtaining incorrect timing.

Connect the timing light according to the manufacturer's instructions. Start the engine and operate at idle speed. Direct the light on the timing mark. It should flash just as the timing mark lines up with the pointer, indicating correct timing. If the pointer and timing mark does not line up, rotate the distributor as required to bring them in alignment.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasketed surfaces between body and air horn. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to a "cutting-out" on turns complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the float and intake needle and seat may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge from pump jets.

Poor Mileage and Engine Loading Complaints

Cases of poor mileage and engine loading may be due in many instances to sluggish choke valve opening during cold driveaway, caused by insufficient vacuum in choke housing, a plugged or restricted heat pipe or inlet in choke cover. To check for this condition, have engine warm and running at slow idle. Remove choke heat pipe and hold a finger over the heat inlet hole (hole is on choke housing on some carburetors). If there is little or no vacuum pull on the finger, check the choke housing for gasket leaks or plugged vacuum passages. If these are OK, check choke vacuum housing and manifold.

Dirty or Rusty Choke Housing

In cases where it is found that the interior of the choke housing is dirty, gummed or rusty while the carburetor itself is comparatively clean, look for a punctured or eroded manifold heat tube (if one is used).

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck either in the open or closed position. Because of this, an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A valve stuck in the "heat-off" position can result in slow warm-up, combustion chamber deposits, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Move the valve up and down a few times to work in the oil. *Never use engine oil for this purpose as it will leave a residue which hampers valve operation.*

Rough Idle & Low Speed Stalling

These engines are equipped with positive sealed type crankcase ventilation which reduces to a minimum condensation and the formation of sludge. The correct operation of the system depends upon the free flow of air from the carburetor air cleaner through the oil filler tube and engine to the control valve mounted in the intake manifold.

Be sure there is no air leakage at the tube connection, and that the oil filler tube cap gasket is in good condition. Always keep the cap locked securely.

Be sure that the ventilator valve, mounted in the intake manifold, operates at all times. Should the valve become clogged with carbon the ventilating system will not operate and a pressure will build up in the engine crankcase which may cause oil loss at the rear main bearing or by the piston rings.

Should the valve fail to seat it will be impossible to make the engine idle satisfactorily. When the valve operates correctly, a slight vacuum is present in the crankcase which is of material assistance in oil control.

Clean the ventilator valve each time the valves are ground or the engine tuned.

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter.*

CARTER CARBURETOR ADJUSTMENTS

Year	Carburetor Model	Float Level	Float Drop	Idle Screw Turns Open	Pump Travel Setting	Fast Idle Setting	Choke Unloader Setting	Choke Setting

CARTER NOTES

METERING ROD

YF—This adjustment must be checked after adjusting pump and each time the carburetor is reassembled. With throttle valve closed, press down on upper end of diaphragm shaft until diaphragm bottoms in vacuum chamber. Metering rod should contact bottom of metering rod well and metering rod arm should contact lifter link at outer end nearest springs and at supporting lug. Adjust by bending lip of metering rod arm to which metering rod is attached.

WGD and WCD—This adjustment must be made after pump adjustment. With throttle valves closed, press down on vacumeter link until metering rods bottom. With rods held down, revolve metering rod arm until lip contacts vacumeter link. Hold in place and tighten set screw.

Fig. ①—YF float level.

②—With bowl cover held upright, distance between free end of float and bowl cover should be as listed. Adjust by bending stop tabs on float arm.

③—With throttle valve closed, press down on upper end of diaphragm shaft until it reaches bottom. Metering rod arm should now contact pump lifter link at outer end and nearest springs. Adjust by bending pump connector link at lower angle.

④—With choke held wide open, lip of fast idle cam should contact boss on body casting. Adjust by bending at offset portion of choke connector link.

Fig. ⑤—WCD float level.

⑥—With throttle valves closed, distance from top of plunger shaft to top of dust cover boss should be as listed. Adjust by bending throttle connector rod.

⑦—With choke valve closed, tighten fast idle screw on high step of fast idle cam until the clearance listed exists between throttle valve and carburetor bore.

⑧—With throttle wide open, there should be the clearance listed between upper edge of choke valve and inner wall of air horn. Adjust by bending unloader lip on throttle shaft lever.

Fig. ⑨—WGD float level. With solid needle $\frac{9}{32}$", with spring loaded needle $\frac{7}{32}$".

⑩—With throttle valves closed, distance from dust cover boss to top of plunger shaft should be as listed. Adjust by bending throttle connector rod.

⑪—Hold choke valve closed, then close throttle. There should now be the clearance listed between throttle valve and carburetor bore. Adjust by bending choke connector rod.

⑫—With throttle valves wide open, close choke valve as far as possible without forcing. There should now be the clearance listed between upper edge of choke valve and inner wall of air horn. Adjust by bending arm on choke trip lever.

Clutch, Transmission and Transfer Case

CLUTCH PEDAL, ADJUST

Jeeps

To adjust the clutch pedal free travel, which should be 1½", lengthen or shorten the clutch control cable as required.

Station Wagons (Except "6-226")

To adjust clutch pedal free travel, which should be 1", turn the threaded connection between the clutch control lever and the clutch control tube lever as required to obtain the desired result.

"6-226"

To adjust the clutch free pedal travel on these models, loosen the two lock nuts on the pedal adjusting rod. Turn the nuts forward to increase or backward to decrease the free travel. After pedal free travel of 1" is obtained, tighten both lock nuts against the adjusting trunnion, being careful not to change the adjustment.

CLUTCH, REPLACE

Both the Auburn and Rockford clutches, Figs. 1 and 2, are used. They are of the single plate, dry disc type, the difference between them being that the Auburn clutch has three springs while the Rockford clutch has six.

When it becomes necessary to replace the clutch assembly or just the driven disc, follow the procedure outlined for removing the transmission or transmission and transfer case from the vehicle.

Note that labor will be saved on all models except "6-226" if the engine is removed from the chassis without the bell housing. Then remove the clutch from the flywheel.

On "6-226" models, which are equipped with a split bell housing, it is advisable to disconnect both the front and rear propeller shafts, pull the transmission and transfer case to the rear sufficiently to clear the shaft from the clutch. Remove the bottom pan from the bell housing and remove the clutch from the flywheel with the engine still in the vehicle.

If only a new driven disc is to be installed, mark both the pressure plate and flywheel so that the assembly may be installed in the same position to maintain clutch balance. When removing the clutch from the flywheel, loosen the attaching screws a turn or two at a time in progression to prevent distortion of the clutch bracket (cover).

Installation is made in the reverse order, being sure to turn the screws a little at a time in progression until all are tight. When installation is complete, adjust the clutch pedal free travel as outlined above.

Fig. 1 Layout of Rockford clutch parts

TRANSMISSION, REPLACE

Jeeps & 4-Wheel Drive Station Wagons

1. Remove front and rear propeller shafts.
2. If vehicle is equipped with a power take-off, disconnect transfer case end of power take-off drive shaft.
3. Disconnect speedometer cable at transfer case.
4. Disconnect brake cable.
5. Support transmission and engine with jacks.
6. Remove nuts holding rear mounting to frame crossmember.
7. Remove transfer case snubbing rubber bolt nut at crossmember.
8. Remove shift lever or remote control rods.
9. Disconnect clutch release cable at bell crank at yoke end.
10. Remove floor board inspection plate.
11. Remove transfer case shift lever pivot pin screw.
12. Remove transfer case shift lever pivot pin and remove levers. If vehicle is equipped with power take-off, remove shift lever plate screws and lift out lever.
13. Remove frame center crossmember.
14. Remove bolts holding transmission to bell housing.
15. Force transmission to right to disengage clutch control lever tube ball joint.
16. Lower jacks under engine and transmission and slide transmission and transfer case toward rear of vehicle until clutch shaft clears bell housing.

Fig. 2 Layout of Auburn clutch parts

Separate Transmission From Transfer Case

1. Drain lubricant from both units.
2. Remove five screws from cover on rear face of transfer case (if equipped with power take-off, remove power take-off shift housing).
3. Remove transfer case main drive gear from rear end of transmission mainshaft.
4. Remove shift tower from transmission.
5. In the absence of a transmission mainshaft retaining plate, loop a piece of wire around the mainshaft just back of the second speed gear, twist the wire and attach one end to right hand front cover screw and the other end to left hand cover screw.
6. Draw wire tightly to prevent mainshaft from pulling out of transmission case when transfer case is removed.
7. Separate the two housings, using care to see that the transmission mainshaft bearing, which bears in both housings, remains in the transmission case.
8. Reverse the removal procedure to attach the transmission to the transfer case and install the assembly in the vehicle.

Two-Wheel Drive Station Wagons

The following outline covers removal of transmission and overdrive. If not so

Fig. 3 Exploded view of transmission. Jeeps and four-wheel drive Station Wagons

equipped, disregard operations pertaining to overdrive.

1. Disconnect remote control rods at transmission.
2. Disconnect two wires from overdrive solenoid. *Tag wires and terminals to assure correct assembly.*
3. Disconnect two wires at overdrive rail switch. *Tag wires and terminals to assure correct assembly.*
4. Disconnect front universal joint, and speedometer cable at transmission. Have available an ordinary cork of correct size to close cable opening to prevent leakage of lubricant.
5. Disconnect overdrive control cable and conduit.
6. Remove rubber mounted saddle support at rear end of overdrive. Use care not to lose spacers. Remove overdrive governor.
7. Place jack under flywheel bell housing and raise it to support weight of housing.
8. Remove frame cross member with rubber insulators attached.
9. Place jack under engine to support engine when transmisson is removed.
10. Thread out four screws attaching transmission to bell housing as far

Fig. 4 Exploded view of transmission. Two-wheel drive models

Fig. 5 Exploded view of transfer case. Jeeps and four-wheel drive Station Wagons

as possible and yet support weight of transmission. Pull transmission back to bolt heads which will provide approximately ¾″ opening between the two housings and at the same time relieve pressure on clutch release fork in bell housing.

11. Use a long screwdriver through opening in side of bell housing to pry clutch release fork from engagement with clutch release bearing carrier.
12. Complete removal of four transmission attaching screws and pull transmission back until clutch shaft clears bell housing and remove the assembly with release bearing carrier attached.

TRANSMISSION REPAIRS

Four Wheel Drive, Fig. 3

1. Drain lubricant from case and clean case with a suitable solvent.
2. If transfer case is attached, remove its rear cover.
3. If equipped with a power take-off, remove the shift unit which replaces the cover.
4. Remove transfer case main drive gear.
5. Remove transmission cover.
6. Loop a piece of wire around mainshaft directly back of mainshaft second speed gear. Twist wire and attach one end to right hand front cover screw and other end to left front screw. Draw wire tightly to prevent mainshaft from pulling out of transmission case when transfer case is removed. Should mainshaft come out, synchronizer parts will drop into bottom of case.
7. Support transfer case and with a rawhide mallet or brass drift and hammer, tap lightly on end of transmission mainshaft to separate the two units. The transmission mainshaft bearing should slide out of transfer case and remain in transmission.
8. Remove drive gear bearing retainer.
9. Remove lock plate and drive countershaft out through rear.
10. Remove mainshaft rear bearing adapter.
11. Remove mainshaft and gear assembly through transfer case opening.
12. Remove countershaft gearset and thrust washers, noting position of washers.
13. Drive reverse idler shaft out rearward and lift out gear.

Assembly Notes

Reverse the order of the above procedure to assemble the transmission, being sure to observe the following precautions:

The countershaft gearset should have from .012″ to .018″ end play when assembled in the case. This clearance is obtained by selective thickness of the rear steel thrust washer, which is avail-

able in two thicknesses. Assemble the larger bronze washer at the front of the case with the lip entered in the slot in the case. The bronze faced steel washer goes next to the gear at the rear end, and the steel washer next to the case. Use a loading sleeve to assemble the countershaft roller bearings.

Two Wheel Drive, Fig. 4

1. Remove cover, front flange and snap rings from pinion bearing.
2. Use puller to remove pinion bearing, using a suitable synchronizer ring protector to take up the thrust and prevent possible damage to the synchronizer.
3. Pull off the companion flange, remove the rear bearing retainer and oil seal, and slide the speedometer drive gear off the shaft.
4. Mark the synchronizer blocker rings, gear and sleeve so that these parts may be reassembled in their original position.
5. Raise the drive pinion over the countershaft gear, pull the mainshaft and bearing rearward and remove the drive gear from the case.
6. Cock the mainshaft to the side as far as possible, disengage and remove the shift forks.
7. Release the mainshaft front snap ring. Grasp the mainshaft parts and slide the shaft through these parts and out through the rear.
8. Remove the lock plate and drive the countershaft out rearward.
9. Lift out the cluster gear and washers, noting the position of these parts.
10. Drive out the shaft and lift out the reverse idler gear.
11. Remove the shift shaft locating pins and take out the shift levers and shafts and oil seals.
12. Assembly may be made in the reverse order, being sure to use new gaskets and oil seals.

TRANSFER CASE

Four Wheel Drive, Fig. 5

In removing the transfer case, follow the procedure outlined under transmission removal. Then dismantle the case as follows:

1. Remove propeller shaft flange, brake assembly and linkage.
2. Remove lower cover.
3. Remove lock plate.
4. Drive intermediate shaft to rear of case, being careful not to lose thrust washers.
5. Remove intermediate gear, thrust washers and roller bearings through bottom of case.
6. Shift front wheel drive to engaged position (shaft forward) and remove poppet plugs, springs and balls on both sides of output bearing cap.
7. Remove output bearing cap together with the universal joint end yoke, clutch shaft, bearing, clutch gear, fork and shift rod. Use care not to lose the interlock.
8. Remove output shaft snap ring and thrust washer.
9. Use a rawhide mallet to drive against the front end of the mainshaft to start the rear bearing from the case. As the shaft is removed, the gears will remain in the case and can be taken out through the bottom, also the snap ring and thrust washer.
10. Remove set screw in sliding gear shift fork and take out the shift rod.
11. Disassemble the front and rear bearing caps as required.

Assembly Notes

Reverse the order of the above procedure to assemble the transfer case. But when rear bearing cap assembly is installed, check the end movement of the mainshaft which determines the adjustment of the tapered roller bearings. For correct bearing adjustment, the shaft should have from .004" to .008" end play. Adjustment is made by selective shim installation between the cap and case. Shims .003", .010" and .031" thicknesses are available for this adjustment. Do not install the rear cap oil seal until the bearings are properly adjusted.

GEARSHIFT, ADJUST

Remote Control Models

To make an adjustment, shift the hand control lever to its neutral position. Align the pin holes in the levers at the bottom of the main shifting rod to hold them in their neutral positions. Disconnect the control rods from the levers at the transmission and place the transmission levers in neutral. Finally, adjust the length of the control rods so that they will just slip into their respective levers on the transmission without moving the levers from their neutral positions.

Service Note

Difficult shifting on two-wheel drive utility vehicles and station wagons may be due to improper installation of the second and high shift rod on the shift lever.

The shift lever, mounted on the lower end of the remote control shift shaft, is provided with two holes. The shift rod should be placed in the outer hole of the lever on six cylinder models and in the inner hole on four cylinder models.

Rear Axle, "Live" Front Axle and Brakes

Refer To Hydraulic Brakes Chapter For Brake Adjustments

REAR AXLE

This rear axle is of the semi-floating, hotchkiss drive type. The drive pinion is the over-hung type, mounted on preloaded taper roller bearings. Sealing of the pinion shaft is accomplished at the front end by a spring-loaded leather seal bearing on the companion flange, which is splined and secured to the pinion shaft by a nut, Fig. 1.

Axle Shaft, Remove

To remove an axle shaft, jack up the wheel and pull off the hub and brake drum. Block the brake pedal in such a manner that it cannot be depressed. Disconnect the hydraulic brake line from the wheel cylinder. Remove the mounting screws and take off the outer oil seal, shims and brake support. The shaft and bearing may then be pulled out of the housing. The inner oil seal may be removed at this time.

Axle Shaft, Install

Replace the shaft and bearings in the reverse order. If the old parts are replaced and the shims have not been disturbed, the end play should be correct when the parts are assembled. However, if a new axle shaft, bearing, differential carrier or housing has been installed, it will be necessary to check the end play.

Axle Shaft End Play, Adjust

Axle shaft end play can be checked when all parts have been replaced except the wheel and hub. To make the check, rap each axle shaft after the nuts are tight to be sure the bearing cups are seated. Then mount a dial indicator on the axle housing with its contact button touching the end of the shaft. Work the shaft in and out by hand and note the reading on the indicator. If an adjustment is necessary, remove the oil seal and brake support and add or remove shims as required to bring the end play to .001" to .005".

When making this adjustment, an equal thickness of shims should be removed or added on each side of the axle housing to maintain the central position of the axle shafts.

Rear Axle Assembly, Replace

Inasmuch as the axle tubes are pressed into the differential carrier to form a one-piece housing, the rear axle assembly must be removed from the chassis when it becomes necessary to overhaul the unit.

1. Raise vehicle from floor and support

Fig. 1 Exploded view of rear axle assembly. All Models

with stand jacks under frame side rails.
2. Remove rear wheels.
3. Split rear universal joint.
4. Disconnect parking brake cable (if equipped) from operating lever and from brake backing plates.
5. Disconnect hydraulic brake line connection at rear axle housing.
6. Loosen and move shock absorbers out of the way.
7. While supporting axle housing with hydraulic jack, remove spring clips and lower axle assembly to the floor.
8. Reverse the foregoing procedure to install the rear axle assembly, being sure to bleed the brake system when the installation is completed.

Differential Carrier, Disassemble

1. Remove axle shafts as outlined previously. Axle shafts may be pulled out only far enough to clear differential side gears.
2. Drain lubricant and remove rear cover.
3. Make sure differential side bearing caps and axle housing are marked, then remove the side bearing caps.
4. Pry differential from housing.
5. Remove side bearing cups.
6. Pull off side bearings and adjusting shims, tagging the shims for identification on reassembly.
7. Unfasten ring gear from case.
8. Drive out differential pinion shaft pin and pull out the shaft, pinions and side gears.
9. Hold companion flange from turning and remove flange nut.
10. Pull flange from pinion shaft.
11. Remove pinion from carrier by tapping on front end with soft hammer.
12. Remove pinion shaft bearing oil seal and bearings from carrier, keeping separate the shim pack at each bearing.

Pinion & Bearings, Replace

If the original ring gear and pinion are being used in the original carrier, use the original shim packs at each bearing, Fig. 2. If a new pinion or differential carrier is installed, note the markings on the end of the pinion gear and on the differential carrier to obtain the correct thickness of shimming to be used with these parts from your supplier. The shims behind the rear bearing establishes the correct pinion depth.

Fig. 2 Rear axle adjustments. All models

1. Press the rear pinion bearing cup in the housing with the proper thickness of shims. Press the rear pinion bearing on the shaft.
2. Install the front bearing cup and shims, and front bearing.
3. Install the companion flange and, while holding the flange from turning, tighten the nut to a torque load of 200-220 lb. ft.
4. Check the pinion bearing pre-load with a spring scale and heavy cord wrapped around the companion flange. Pull on the spring scale. The torque required to rotate the pinion is 10-30 inch lbs. If not within these limits, add or remove shims from behind the front bearing to obtain the proper pre-load.
5. Remove the companion flange and install a new oil seal (well soaked). Reinstall the companion flange and tighten the nut.

Ring Gear, Replace

1. Install guide pins in every other hole in the ring gear. These pins can be made from 1½″ long capscrews with heads cut off and ends slotted.
2. Make sure back face of ring gear and face of case are free of dirt and

Fig. 3 "Live" front axle. Jeeps and four-wheel drive Station Wagons

burrs and slip gear over pilot diameter of case.

3. Install every other ring gear bolt. Draw them up evenly and snugly so ring gear face is flush with case.
4. Remove guide pins and install remaining bolts.

Differential Carrier, Assemble

The differential bearings are adjusted by shims, Fig. 2. These shims also establish the ring gear position with the pinion. Therefore, backlash must be checked whenever a bearing adjustment is made.

The correct bearing adjustment is one which will provide a .008″ pinch fit when the differential unit is assembled into the carrier. To make the adjustment, install the bearing cones without shims and place the assembly in the housing with the bearing cups. Force the unit to one side and check the clearance between the bearing cup and differential case with a feeler gauge. When the clearance is determined, select shims of this amount plus .008″ extra to establish the proper pre-load.

Remove the differential bearings again and divide the shims into two packs of equal thickness and install on each side and replace the bearings. Reinstall the unit in the carrier. This operation is made easier by cocking the bearing cups slightly when the differential is placed in the housing and then tapping them lightly with a mallet. However, when installing the differential in the housing, be sure the ring gear teeth mesh with the pinion teeth before tapping the bearings in place.

After the bearing cups are firmly in place, install the bearing caps. The bearing caps and gasket surface of the housing are marked with a horizontal numeral and on the other side by a vertical numeral. The position of the numerals should correspond when reinstalling the bearing caps.

Ring Gear & Pinion Backlash, Adjust

Mount a backlash gauge indicator on the carrier and start checking for the correct backlash between the ring gear and pinion. If the backlash is not within the limits of .004″ to .009″, it will be necessary to change the arrangement of the shims back of the bearings. Make corrections in backlash, as described for this type axle in the *Rear Axle Chapter,* bearing in mind that shims removed from one side must be installed on the opposite side so that the total shim thickness of the right and left side will remain unchanged, and the bearing adjustment undisturbed.

Gear Tooth Contact Pattern

Allowable variations in the carrier or drive pinion may cause the pinion to be too far in or out even when shimmed properly. Thus, the tooth contact must be tested and corrected as necessary or the gears may be noisy.

Paint the ring gear teeth with a light coating of red lead, white lead or prussian blue. Revolve the gears and observe the contact, referring to the illustrations shown in the *Rear Axle Chapter* for this operation.

Installation in Vehicle

To install the axle under the vehicle, have the end of the vehicle securely supported with a chain hoist or a support under the frame just ahead of the rear springs. Place the axle assembly in position and raise it so the spring clips and front spring bolts may be installed. Connect the brake line hose at the frame, install lock clip and attach brake line. Connect the propeller shaft at the rear universal joint. The wheels may then be installed and the vehicle lowered to the floor. Bleed the brakes to remove any air from the lines.

"LIVE" FRONT AXLE

Four-Wheel Drive Models, Fig. 3

The front axle on these models is a live driving unit with hypoid driving gears and spherical steering knuckles mounted on pivot pins which ride on tapered roller bearings for ease of steering. The drive is of the full-floating type through axle shafts built integrally with constant velocity universal joints which revolve in the steering knuckles.

Fig. 4 Bendix type axle shaft and universal joint. For "live" front axles

Fig. 5 Rzeppa type axle shaft and universal joint. For "live" front axles

Front Axle Service

The differential is mounted in a housing similar to that used in the rear axle except that the pinion shaft faces toward the rear instead of to the front and to the right of the center of the axle. This design allows the placing of the front propeller shaft along the right side of the engine oil pan to avoid reducing road clearance under the engine.

The axle is of the full floating type and the axle shafts can be removed without dismantling the steering knuckle housing.

Overhaul of this axle unit is the same as the rear axle.

Service Note (Axle Shafts)

A change in design of the front axle on four-wheel drive vehicles was placed in production effective with the following serial numbers:

No. 37549 on CJ-3A

No. 44070 on 4WD

No. 14284 on 4x463

In the new design the front axle shaft outer splined end floats in the wheel driving flange and is not retained by a nut and lockwasher as originally used. With this construction it is no longer necessary to install shims between the driving flange and wheel hub to provide the correct end float of the axle shaft universal joint.

The new construction, when using the Bendix type axle shaft, is shown in Fig. 4. Note that the end float of the Bendix type joint is predetermined in manufacture by the position and flange thickness of the bushing and thrust washer. These parts are so positioned and of the correct thickness to provide .088″ maximum end float of the universal joint to operate at the centerline of the spindle pivot pins. With the correct joint end float controlled by the bushing flange and thrust washer, it is no longer necessary to install shims between the driving flange and wheel hub, a gasket only being used.

The new type Bendix axle shaft and universal joint may be readily installed in an old type axle by installing the new type flanged bushing. When this is done, discard the shims previously installed between the flange and hub, installing a gasket only. The flanged bushing requires no reaming and is so designed that when it is pressed into the spindle it will be compressed to provide correct running clearance. Coat the inner surface of the bushing with chassis grease before installing the spindle.

The axle construction is similar for installation of the Rzeppa joint, Fig. 5. The thrust washer is not necessary although it is installed in all axles to allow installation of the Bendix type shaft if so desired. As the thrust washer is not effective, a snap ring is installed at the outer end of the shaft to control end float.

Steering Knuckle Pivot Pins

When reinstalling a steering knuckle, sufficient shims must be installed under the bearing caps so the proper tension will be obtained on the bearings. The shims are available in thicknesses of .003″, .005″, .010″ and .030″.

Install one each of the shims over the studs on the steering knuckle at the top and bottom. Install the bearing caps, lock washers and nuts and tighten securely. Check the tension of the bearings by hooking a spring scale in the hole in the arm for the tie rod socket. The load should be 6-9 lbs. without the oil seal in position and is secured by adding or removing shims as required. Make sure there are the same thickness of shims between the upper cap and the knuckle as between the lower cap and knuckle.

Service Note (Lower Shims)

On models CJ-3A, 473-4WD and 4x473, .058″ was added to the bottom face of the king pin boss on the steering knuckles. This eliminated the shims for the lower kingpin bearing and the adjustment of the bearing is now made by shims at the top only.

BRAKE MASTER CYLINDER, REPLACE

To remove the master cylinder, disconnect the fluid lines and stop light wires from the cylinder. Unfasten the cylinder from its mounting. Remove the eye bolt from the shaft and drop the cylinder from its mounting.

Front End and Steering Section

CAMBER & CASTER

Two-Wheel Drive Station Wagons

Camber is adjusted by adding or removing shims as required from behind the upper control arm frame bracket, Fig. 1.

Caster is controlled by the relationship between the position of the front spring and its location in the frame cross member channel. If caster is out, examine the suspension for worn or damaged parts.

TOE-IN, ADJUST

Two-Wheel Drive Station Wagons

Load the front end of the vehicle by weights or persons so that the front spring main leaf is flat. Flatness of the front spring main leaf may be checked by holding a straight edge or string below the main leaf, and parallel with it.

Roll the vehicle backward and forward so that all parts will attain a normal position. With suitable trams or gauge, measure the distance between the wheels at the rear and then at the front. These measured distances should be equal (for zero toe-in).

If the distances are not equal, readjust the tie rods as required to make the distance equal.

When the load is removed from the front of the vehicle, it will be found that the wheels will attain a slight toe-in, ranging from $\frac{1}{8}$ to $\frac{3}{16}$ in., depending upon the arch of the front spring. This is normal and will give satisfactory results in respect to tire wear and proper handling of the vehicle.

HORN SOUNDER & STEERING WHEEL

Remove the horn button or steering wheel hub cover by turning it about ⅛ turn to the left and disengaging.

After removing the horn button and ring, use a suitable puller to pull off the steering wheel.

STEERING GEAR, REPLACE

Jeeps & Station Wagons

It is necessary to pass the steering gear down through the floor pan. The procedure is as follows:

1. Remove left front fender on CJ-2A.
2. Disconnect remote control rods from levers on steering column if equipped with steering post shift.
3. Remove horn button and steering wheel.
4. Remove steering post bracket at instrument panel.
5. Remove steering post hand lever.
6. Remove exhaust pipe from manifold.
7. Remove steering column cover plate on toe board.
8. Remove two screws attaching remote control housing to steering column.
9. Remove horn wire contact brush (CJ-2A) or disconnect horn wire.
10. Remove remote control gearshift assembly down through floor pan.
11. Remove pitman arm from steering gear.
12. Unfasten steering gear from frame and bring it down through the floor pan and over the outside of the frame side rail.

STEERING GEAR REPAIRS

This steering gear, Fig. 2, is the cam and twin lever type in which the cam is

FRONT END REPAIRS

Two-Wheel Drive Station Wagons Kingpins & Bushings

The following text applies to earlier models insofar as this operation is concerned.

1. Remove wheel hub and dust caps.
2. Take off wheel and hub, bearings and oil seal.
3. Disconnect hydraulic brake tube and remove brake backing plate with brake assembly attached.
4. Drive out kingpin lock pin.
5. Use a sharp drift to remove the kingpin lower expansion plug.
6. Use a brass drift to drive the kingpin up until the upper needle bearing is removed.
7. Use a brass drift to drive the kingpin out through the bottom.
8. Remove the bushing from the lower part of the spindle.

Assembly is the reverse of the above. When reaming the bushing to size, use a pilot type reamer to be sure that the bushing is square with the upper needle bearing. Examine the ball thrust bearing and replace it if worn or damaged. Do not overlook bleeding the brakes.

Steering Knuckle Supports

Should it be necessary to disassemble the front suspension, be sure that the steering knuckle supports are reinstalled on the proper side. The left support will interchange with the right but the wheel camber will be incorrect, resulting in unstable steering. The supports have the part number on the forging for identification—641026 left side, 641027 right side. Later production parts may be identified by the letter L for left and R for right.

When mounting the upper control arm pin bushing in the steering knuckle support, tighten it to 175 lbs. ft. torque. Centralize the control arm over the knuckle support before starting to thread the pivot pin through the support. This is necessary to provide the proper caster effect and equal clearance at each side of the support for the rubber dust seals. Also for the same reasons centralize the spring eye in the lower end of the knuckle support before starting the spring pivot bolt.

Fig. 2 Steering gear adjustments

mounted on ball bearings and the lever shaft turns on steel backed bronze bushings.

As the cam is turned by the wheel tube, the follower studs are pulled along the cam groove, causing the lever arm to rotate the lever shaft. The groove in the cam is cut shallower in the straight-ahead driving position to provide closer adjustment between the studs and the cam where most of the steering action occurs.

Cam End Play, Adjust

1. Free the steering gear of all load by disconnecting the drag link and loosening the steering column braces.
2. Loosen the lock nut adjusting screw in the side cover to free the studs in the cam groove.
3. Remove the upper cover stud nuts and raise the housing upper cover to permit removal of the adjusting shims, which are .002″, .003″ and .010″ thickness.
4. Clip and remove one thin shim, tighten down the cover and check the adjustment. There should be a slight drag but the steering wheel should turn freely with the thumb and forefinger lightly gripping the rim. If necessary, remove or replace shims until the adjustment is correct.

Lever Shaft Backlash, Adjust

1. Centralize the steering gear by turning the wheel all the way to the right. Then, starting from this point, count the number of turns required to reach end of travel to the left. Turn the wheel back half this number of turns to the mid-position.
2. Tighten the side cover adjusting screw until a very slight drag is felt through the mid-position when turning the steering wheel slowly from one side to the other. The gear should not bind in any position but a slight drag should be felt in the mid-position only.
3. After proper adjustment is secured, tighten the lock nut and give the gear a final check for binding.

DESCRIPTION

This transmission, Fig. 1, embodies many features of the familiar cast iron Powerglide, the discontinued Turboglide and the Corvair Powerglide transmission. Driving characteristics remain the same as found in the cast iron Powerglide with the single shift occurring between low and drive. However, design and appearance of the internal components are somewhat changed.

The conventionally arranged torque converter is a welded unit, eliminating the possibility of internal servicing. Low (band) and drive (disc clutch) functions are performed by a new clutch drum assembly which differs from the cast iron Powerglide primarily in that multiple release springs are incorporated in place of the large single spring.

The planetary gearset, while greatly strengthened, operates in the same manner as the cast iron Powerglide gearset. The reverse clutch is of the disc type operated by a reverse clutch piston and incorporating multiple return springs. The governor is radically different from that used in the cast iron Powerglide in that it completely encircles the output shaft and spins with the shaft.

The valve body has been relocated to the bottom of the case where service operations on it may be performed without the necessity of removing the transmission from the vehicle. A parking lock similar to that found in the Turboglide is used.

MAINTENANCE

Oil Level

The transmission oil level should be checked every 1000 miles. Oil should be added only when the level is near the "Add" mark on the dipstick with oil hot or at operating temperature.

In order to check oil level accurately, the engine should be idled with the transmission oil hot and the control lever in neutral "N" position.

It is important that the oil level be maintained no higher than the "Full" mark on the oil level gauge. *Do not overfill for when the oil level is at the full mark on the dipstick, it is just slightly below the planetary gear unit. If additional oil is added, bringing the level above the full mark, the planetary unit will run in the oil, foaming and aerating the oil. This aerated oil carried through the various oil pressure passages may cause malfunction of the transmission assembly, resulting in cavitation noise in the converter and improper band or clutch application.*

Changing Oil

Transmission fluid installed at the factory is good for the life of the vehicle. It is not necessary to replace the fluid except to make additions when needed to bring it to the proper level. When the transmission is to be removed for repairs, drain and refill as follows:

To drain the transmission, carefully loosen the oil pan bolts. Position a receptacle to catch the draining oil. If the transmission is to be removed for repairs, the draining operation may be performed after removal, if desired.

To refill the transmission, remove the dipstick from the filler tube and refill the transmission with approved fluid. The engine should then be run at a fast idle speed with the transmission in neutral until the oil warms up. Then add oil as required to raise the fluid level on the dipstick to the "Full" mark. Refill capacity is 1½ quarts. Total capacity including converter is 9 quarts.

"In Car" Repairs

OIL PRESSURE CHECKS

Five basic pressure checks are used for diagnosis and operational checks of the transmission. All checks should be made with the transmission thoroughly warmed up. It is not recommended that stall tests be conducted which would result in engine vacuum falling below 10" Hg.

Pressure gauge hose connections should be made at the low servo apply (main line) and reverse test points, Fig. 2.

Wide Open Throttle Upshift Check

Wide open throttle upshift should occur at 85-95 psi as indicated on the low servo apply (main line) gauge.

Idle Pressure in "Drive" Range

In addition to the oil pressure gauges, a vacuum gauge is needed for this check. With the parking brake applied and shift lever in "Drive", low servo apply (main line) pressure should be 62-73 psi with 16" of vacuum; 85-95 psi with 10" of vacuum.

If pressures are not within these ranges, the following items should be checked for oil circuit leakage.

- Pressure regulator valve stuck.
- Vacuum modulator valve stuck.
- Booster valve stuck.
- Leak at low servo piston ring (between ring and bore).
- Leak at low servo piston rod (between rod and bore).
- Leak at valve body-to-case gasket.
- Leak at valve body gaskets.
- Front pump clearances.
- Check passages in transmission case for porosity.

POWERGLIDE (Aluminum Case)

Fig. 2 Oil pressure check points

Fig. 3 Vacuum modulator, gasket and valve

Manual "Low" Range Check

Connect a tachometer and apply the parking brake. Place selector lever in "Low" range and adjust engine speed to 1000 rpm with car stationary. Low servo apply (main line) pressure should be 126-131 psi. Pressures not within this range can indicate the following possibilities:

- Partially plugged oil suction screen.
- Broken or damaged ring in low servo.
- Pressure regulator valve stuck.
- Leak at valve body-to-case gasket.
- Leak between valve body gaskets.
- Leak at servo center.
- Front pump clearances.

Drive Range Overrun (Coast) Pressure

With the vehicle coasting in "Drive" range at 20-25 mph with engine vacuum at about 20" vacuum, low servo apply (main line) pressure should be 48-54 psi.

Reverse Pressure Check

With parking brake applied, place selector lever in "Reverse" and, using a vacuum gauge, reverse pressures should be 106-124 psi with 16" vacuum; 147-153 psi with 10" vacuum. If pressures are within limits but operation in reverse is faulty, the reverse clutch pack probably needs replacing which requires a transmission overhaul. If pressures are below the limits, the following items should be checked.

- Partially plugged oil suction screen.
- Split or damaged reverse servo piston ring.
- Pressure regulator valve or booster valve stuck.
- Leak at valve body-to-case gasket.
- Leak between valve body gaskets.
- Front pump clearances.

Fig. 4 Valve body attaching bolt sizes

VALVE BODY

1. To remove, take off oil pan and gasket.
2. Remove vacuum modulator components, Fig. 3.
3. Remove two bolts attaching detent guide plate to valve body and transmission case. Remove guide plate and range selector detent roller spring.
4. Remove remaining valve body attaching bolts, Fig. 4, and carefully lift out valve body and gasket, disengaging the servo apply tube from the transmission case as the valve body is removed.

Disassemble

1. Referring to Fig. 5, remove manual valve, suction screen and gasket.
2. Remove cover bolts and carefully remove lower valve body and transfer plate from upper valve body. Discard gaskets.
3. Remove front and rear pump check valves and springs.
4. From upper valve body, remove TV and detent valves and downshift timing valve as follows: Remove retaining pin by wedging a thin screwdriver between its head and the valve body, then remove detent valve and throttle valve spring. Tilt valve body to allow throttle valve to

Fig. 5 Layout of valve body components

fall out. If necessary, remove the "C" clip and disassemble the detent valve assembly. *Do not disturb the setting of the adjustment hex nut on the detent valve assembly.* This is a factory adjustment and should not normally be changed. However, some adjustment is possible (see Throttle Valve Adjustment below).

5. Drive out roll pin, remove valve spring and downshift timing valve.
6. From the lower valve body, remove low-drive shift valve and pressure regulator valve as follows: Remove snap ring and tilt valve body to remove low-drive regulator valve sleeve and valve assembly, valve springs and shifter valve. Remove snap ring and tilt body to remove hydraulic modulator valve sleeve and valve, pressure regulator valve spring seat, spring, damper valve, spring seat and valve.

Inspection

Since most valve body failures are caused initially by dirt or other foreign material preventing a valve from functioning properly, a thorough cleaning of all parts in clean solvent is mandatory. Check all valves and their bores for burrs or other deformities which could result in valve hang-up.

Assemble

1. Referring to Fig. 5, replace valve components in proper bores, reversing disassembly procedures given above.
2. Place front and rear pump check valves and springs into place in upper valve body and install gasket and transfer plate.
3. Carefully install lower valve body and gasket and install fifteen 1⅜" attaching bolts and torque to 8 to 11 ft. lbs., Fig. 4.

Installation

1. With manual linkage and selector lever detent roller installed, place valve body in position (servo apply tube installed) with a new gasket. Carefully guide servo apply line into its boss in the case as the valve body is set in place. Install six mounting bolts and range selector detent roller spring shown in Fig. 4. *Position manual valve actuating lever fully forward to more easily pick up the manual valve.*
2. Install guide plate, making sure that inner lever properly picks up manual valve. Install attaching bolts.
3. Install vacuum modulator valve, modulator and gasket.
4. Install oil pan with new gasket.

VACUUM MODULATOR

Remove and install vacuum modulator, which is mounted on left rear side of transmission, Fig. 3. Check the valve for nicks and burrs. If such cannot be repaired with slip stone, replace the valve.

Fig. 6 Low band adjustment

Fig. 7 Throttle valve adjusting nut

The modulator can be checked with a vacuum source for leakage. However, leakage normally results in transmission oil pull-over and results in oil smoky exhaust and continually low oil level. No vacuum modulator repairs are possible; replace as an assembly.

Installation

1. Install vacuum modulator valve in transmission bore.
2. Place a new gasket on modulator and hold gasket centered with vaseline. *This is important to prevent a transmission external oil leak.*
3. Install vacuum modulator, tighten firmly and install vacuum line as shown in Fig. 3. Rubber tubing "A" should bottom against modulator can. Pipe "B" should bottom against modulator extension.

LOW BAND, ADJUST

Tighten the low band adjusting screw to 40 inch lbs with a torque wrench, Fig. 6. Then back off four complete turns and tighten lock nut. *The amount of back-off is not an approximate figure; it must be exact.*

If the adjustment is being made during transmission overhaul, the input and output shafts must be turned simultaneously to properly center the band on the clutch drum.

THROTTLE VALVE, ADJUST

No provision is made for checking TV pressures. However, if operation of the transmission is such that some adjustment of the throttle valve is indicated, pressures may be raised or lowered by adjusting the position of the jam nut on the throttle valve assembly, Fig. 7.

To raise TV pressure 3 psi, back off the jam nut one full turn. This increases the dimension from the jam nut to the TV valve stop. Conversely, tightening the jam nut one full turn lowers TV pressure 3 psi.

A difference of 3 psi in TV pressure will cause a change of approximately 2 to 3 mph in the wide open throttle upshift point. Smaller pressure adjustments can be made by partial turns of the jam nut. The end of the TV adjusting screw has an allen head so the screw may be held stationary while the jam nut is moved. *Use care when making this adjustment since no pressure tap is provided to check TV pressure.*

Repairs Requiring Transmission Removal

DISASSEMBLE TRANS.

Extension, Governor and Rear Pump

1. If replacement is necessary, remove speedometer driven gear.
2. Remove transmission extension. Note seal ring on rear pump body.
3. Remove speedometer drive gear.
4. Remove "C" clip from governor shaft on weight side of governor. Then remove shaft and governor valve from opposite side of governor, Fig. 8, and two belleville springs. Loosen governor drive screw and slide governor off output shaft.
5. Remove rear pump body from case (4 bolts), also drain-back baffle extension seal ring, drive and driven gears. *When drive gear is removed, the drive pin may fall out if the hole is on the bottom of the shaft and the shaft is horizontal. It is of extreme importance that the oil pump drive pin be removed, Fig. 9.*
6. After removing drive pin, remove rear pump wear plate.

Internal Components

1. Remove seven front oil pump bolts. Bolt holes are offset to insure proper installation.
2. Remove front pump and stator shaft and selective fit thrust washer with tools shown in Fig. 10. Two threaded holes are provided to mount the pullers. Remove pump ring seal and gasket. *Note that pump bolts have special "O" rings which must be in place upon installation.*
3. Release tension on low band adjustment. Then grasp transmission input shaft and carefully work it and the clutch drum out of the case, Fig. 11. *Use care not to lose the low sun gear (splined) bushing from input shaft.* The low sun gear thrust washer will probably remain in the planet carrier.
4. Remove low band and struts.

Fig. 8 Removing governor valve and shaft

Fig. 10 Removing front oil pump. The pullers shown are made of two 3/8-16 x 10" stove bolts

Fig. 9 Removing rear oil pump drive pin. When installing the pin, be sure to index it with the gear

Fig. 11 Removing clutch drum and input shaft

5. Remove planet carrier and output shaft caged bearing from front of transmission.
6. Remove reverse ring gear.
7. Using a large screwdriver, remove reverse clutch pack retainer ring and lift out reverse clutch plates. *If difficulty is experienced in getting snap ring past shoulder on reverse pack pressure plate, a feeler gauge may be used as a guide.*
8. Install the tool shown in Fig. 12 or equivalent through the rear bore of the case to compress the rear piston spring retainer and springs in order to remove the snap ring. Remove the tool and then the retainer and 17 piston return springs.
9. Remove rear piston by applying air pressure to the reverse port in the rear of the transmission case, Fig. 13. Remove inner and outer seals.
10. Remove servo cover, piston and spring.
11. Remove oil pan, valve body and vacuum modulator as described in the "In Car" Repairs section of this chapter.

CONVERTER

The converter is a welded assembly and no internal repairs are possible. Check the seams for stress or breaks and replace converter if necessary.

FRONT PUMP

1. Remove pump cover from pump body.
2. Remove pump gears from body. Do not drop or nick gears as they are not heat treated. See Fig. 14 for layout of pump parts.
3. Remove rubber seal ring from body.

Inspection

1. Wash all parts and air dry. Inspect

Fig. 12 Removing rear piston spring retainer snap ring

Fig. 13 Applying air pressure to remove rear piston

all parts for nicks, scoring or other damage.
2. Check operation of priming valve.
3. Check clearance between body bushing and converter pump hub. Maximum clearance is .005″. If bushing is damaged, front pump body should be replaced.
4. If oil seal is damaged or is leaking and pump body is otherwise suitable for reuse, pry out and install a new seal. Outer diameter of seal should be coated with a non-hardening sealer prior to installation.
5. Check condition of oil cooler by-pass and lube relief valves. Replace if either valve leaks excessively.
6. Check pump clearances with feeler gauge. If clearances exceed the following specifications, replace parts as required.
   a. Clearance between O.D. of driven gear and body should be .0035-.0065″.
   b. Clearance between I.D. of driven gear and crescent should be .003-.009″.
   c. Gear end clearance (between gears and pump body) should be .0005-.0015″.

Assembly

1. Referring to Fig. 14, and with transmission facing up, remove input shaft, clutch drum, low band and struts as outlined under disassembly procedure.
2. Install downshift timing valve (conical end out) into pump cover.
3. Oil gears generously and install in pump body.
4. Carefully set pump cover in place over body and loosely install two attaching bolts.
5. Place pump assembly (less rubber seal ring) upside down into pump bore of case (use guide pins if desired). Install remaining attaching bolts and torque to 15-20 ft. lbs.
6. Remove pump from case. Replace clutch drum and input shaft, low band and struts.
7. Install rubber ring seal in its groove in pump body and reinstall pump, using a new gasket. Be sure that the selective fit thrust washer is in place.
8. Install attaching bolts, using new bolt "O" rings is necessary.

REAR PUMP

The rear pump is removed and disassembled as described in the disassembly procedure. General cleaning and clearance check information is the same as for the front pump. Assembly of the rear pump will be covered during the reassembly of the transmission.

If the rear pump bushing requires replacement, press or drive the bushing in from the front of the pump.

CLUTCH DRUM

When working with the clutch drum, use extreme care that the machined face on the front of the drum, Fig. 14, not be scratched, scored, nicked or otherwise damaged during any of the following operations. This machined face must be protected whenever it must be brought to bear on a press or tool of any sort.

Disassemble

1. Remove retainer ring and low sun gear and clutch flange from clutch drum.
2. Remove hub rear thrust washer.
3. Remove clutch spring retainer using the tool shown in Fig. 15 or an arbor press. Compress springs far enough to allow removal of snap ring. Then, releasing pressure on springs, remove retainer and 24 springs.
4. Lift up on piston with a twisting motion to remove from drum, then remove inner and outer seals.

Inspection

1. Wash all parts and air dry.
2. Check drum bushing for excessive wear or damage.
3. Check the steel ball in clutch drum that acts as a relief valve. Be sure it is free to move in the hole and that the orifice leading to the front of the drum is open. *If the ball is loose enough to come out or not loose enough to rattle, replace the clutch drum as an assembly. Replacing and restaking of the ball should not be attempted.*
4. Check fit of clutch flange in drum slots. There should be no appreciable radial play between these two parts. Also check low sun gear for damage and the bushing for wear. Remove and install the bushing as shown in Fig. 16. Press in bushing only far enough so that the tool meets the clutch drum.

Assembly

1. Install new piston inner seal in hub of drum with lip seal downward (toward front of transmission).
2. Install a new seal in piston. Seal lips must be pointed toward clutch drum. Lubricate seals generously and in-

Fig. 14 Internal mechanism of transmission

stall piston in drum with a twisting motion.

3. Place 24 springs in position on the piston, then place retainer in place on springs.
4. Depress retainer plate and springs far enough to allow installation of the retainer snap ring in its groove in the drum hub.
5. Install hub front washer with its lip toward clutch drum, then install clutch hub.
6. Install five steel reaction plates and four faced plates alternately, starting with a steel plate.
7. Install rear hub thrust washer with its flange toward low sun gear. Then install low sun gear and flange and secure with retainer ring. When installed, the openings in retainer ring should be next to one of the lands of the clutch drum.
8. Check assembly by turning clutch hub to be sure it is free to rotate.

LOW BAND

The band used in this transmission has bonded linings which, due to the transmission characteristics and band usage, should require very little attention. However, whenever a transmission is disassembled the band should be cleaned of metal particles and inspected for evidence of scoring or burning, band and lining for cracks, and band linkage for excessive wear.

INPUT SHAFT & PLANET UNIT

1. Wash assembly and air dry all parts. Be sure to blow out all oil passages.
2. Inspect all parts for nicks or other damage.
3. Check end clearance of planet gears, Fig. 17.
4. Check fit of input shaft in clutch hub and reverse sun gear. Also check fit of splines in turbine hub.
5. Check oil seal rings for damage; they must be free in input shaft ring grooves.
6. Remove rings and insert in stator support bore and check to see that hooked ring ends have clearance. Replace rings on shaft.

Repairs

1. In repairing the planet carrier assembly, refer to Fig. 18 and note the following precautions.
2. Place the assembly in a fixture or vise so that the front of the assembly (parking lock gear end) faces up.
3. Using prick punches, mark each pinion shaft and also planet carrier so that when reassembling, each pinion shaft will be reinstalled in the same location from which it was removed.
4. Use care so as not to lose any of the planet pinion needle bearings. Twenty needle bearings are used with a bearing spacer at each end of the short pinions. Twenty needle bearings are also used in each end of the long pinion, separated by a bearing spacer in the center.
5. When assembling the needle bearings, use dummy pinion shafts to hold bearings and vaseline to hold them in position.
6. The long planet pinions are located opposite the closed portions of the carrier, while the short pinions are located in the openings.
7. When assembling, select the proper pinion shaft (as marked previously). Lubricate the shaft and install it from the top, pushing the dummy shaft ahead of it. As the tool is pushed down, be sure it picks up the lower thrust washer. Turn the pinion shaft so that the slot or groove at the upper end faces the center of the assembly. With a brass or soft steel drift, drive the pinion shaft in until the lower end is flush with the lower face of the carrier.
8. When all pinions are installed, place the pinion shaft lock plate in position. Then with the extended portions of the lock plate aligned with slots in the pinion shafts, rotate lock plate clockwise until the three attaching screw holes are accessible. Install screws and torque to 2½-3 ft. lbs.

Fig. 15 Removing clutch spring retainer snap ring

Fig. 16 Removing and installing clutch drum bushing

Fig. 17 Checking planet gear end clearance (.006" to .030")

GOVERNOR

The governor, Fig. 19, is a factory balanced unit. If body replacement is necessary, the two sections must be replaced as a unit. Note that the governor valve and shaft were already disassembled during the removal procedures.

Remove outer weight by sliding it toward center of body. Remove smaller inner weight and spring after removing snap ring. If it is considered necessary, remove body bolts and separate body, hub and gasket. Remove two seal rings.

Inspection

Clean all parts and air dry. Check condition of all parts and replace any that are bent, damaged or scored. Body and hub must be replaced as a unit.

Assembly

1. Referring to Fig. 19, reassemble governor weights and install in body bore. Replace seal rings on hub.
2. Slide hub on output shaft and lock in place with drive screw. Install gasket and governor body over output shaft. Install governor shaft, lining it up properly with output shaft and install attaching bolts. Torque bolts to 6-8 ft. lbs. *Place transmission selector lever in Park position to keep shaft from turning when tightening bolts.*
3. Check governor weight for free fit in body after bolts are torqued. If weight sticks or binds, loosen bolts and retorque.

TRANSMISSION, ASSEMBLE

Figs. 20 and 21 picture the transmission case components and manual levers. In assembling the transmission, use only transmission oil or vaseline as lubricants to retain bearings and races during assembly. Lubricate all bearings, seal rings and clutch plates prior to assembly.

1. If removed, assemble manual linkage as suggested by Fig. 21.
2. Install inner and outer rear piston seals on reverse piston and, lubricating piston and case with transmission oil, install piston into case. If necessary, carefully slide a feeler gauge around the outer diameter of the piston to start the seal ring into the bore.
3. With the transmission facing up, install 17 reverse piston springs and their retainer ring.
4. With the tool shown in Fig. 12, compress reverse piston springs enough to allow installation of retaining snap ring. *Use care when performing this operation that the spring retainer is correctly guided over case internal hub and is not damaged by catching on edge of hub or in snap ring groove.*
5. Install reverse clutch pack, Fig. 22, beginning with a reaction (spacer) plate and alternating with the drive (faced) plate until six reaction plates and six drive plates are in place. The notched lug on each reaction plate is installed in the groove at the 7 o'clock position in the case. Then install the thick pressure plate which has a "dimple" in one lug to align with the same slot in the case as the notched lugs on the other reaction plates.
6. Install clutch plate retaining ring.
7. Check for correct selective reverse reaction spacer plate running clearance as follows:
   a. position transmission in horizontal position.
   b. Using feeler gauges, measure clearance between any reaction plate and adjacent faced plate. Because the faced plate is waved, it will be necessary to slide the feeler gauges in an arc of several inches to get an average reading.
   c. If the proper spacer is installed, gauge measurement will be .025-.060".
   d. If clearance is not within limits, remove reverse clutch pack and install a thicker or thinner reverse spacer plate, as required, next to piston. Then recheck running clearance. Reverse spacers are available in three sizes: .068-.070", .100-.104", and .132-.136".
8. With rear of transmission down-

Fig. 18 Disassembled view of planet carrier assembly

Fig. 19 Disassembled view of governor

ward, align internal lands and grooves of reverse faced plates, then engage reverse ring gear with these plates. This engagement must be made by "feel" while jiggling and turning ring gear.

9. Place thrust bearing over output shaft and install planetary carrier and output shaft into case.
10. Install thrust washer on low sun gear in gearset with flange of thrust washer toward front of case. Use vaseline to keep washer in place.
11. Move transmission to horizontal position. The two input shaft seal rings should be in place on shaft. Install clutch drum (machined face first) onto input shaft and install low sun gear bushing (splined) against shoulder on shaft.
12. Install clutch drum and input shaft into case, aligning thrust washer on input shaft and indexing low sun gear with short pinions of planet carrier.
13. Remove rubber seal ring from front pump body and, using guide studs, install front pump and gasket and selective fit thrust washer into case. Install two pump-to-case bolts.
14. To check for correct thickness of selective fit thrust washer, move the transmission so the front end is up and proceed as follows:
    a. Mount a dial indicator so that its plunger rests on end of input shaft and zero the dial indicator.
    b. Push up on transmission output shaft and observe total indicator movement. Indicator should read .030-.054″.
    c. If reading is not within these limits, remove the front pump and change to a thicker or thinner thrust washer as required to obtain the proper clearance. Washers are available in thicknesses of .061″, .078″ .092″ and .106″.

Fig. 20 Disassembled view of transmission case and component parts

Fig. 21 Inner control levers, parking pawl and bracket

Fig. 22 Installing reverse clutch plates. Chevy II transmissions have less plates than shown. A belleville spring is used at the rear of the clutch plates on Chevy II units

15. Install servo piston, ring and spring into servo bore. Then using a new gasket and "O" ring, install servo cover.
16. Remove front pump and selective thrust washer and install the low band, anchor and apply struts into the case. Tighten the low band adjusting screw enough to prevent struts from falling out of case.
17. Place seal ring in groove around front pump body and the two seal rings on the pump cover extension. Install pump, gasket and thrust washer into case. Install pump bolts with "O" rings and torque to 13-17 ft. lbs.
18. Turn transmission so its rear end is up and install rear pump wear plate, drive pin and drive gear, *indexing gear to drive pin.*
19. Install rear pump body and driven gear drain-back baffle, and pump-to-case attaching bolts.
20. Install governor over output shaft. Install governor shaft and valve, two Belleville washers (large end of washers against output shaft), and retaining "C" clips. Center shaft in output shaft bore and tighten governor hub drive screw.
21. Install speedometer gear. Place seal ring over rear pump body and install transmission extension.
22. Install valve body and vacuum modulator as already described.
23. Install oil pan and converter.
24. Install transmission in vehicle. Fill transmission with approved fluid in a manner described at the beginning of this chapter. Adjust the low band as previously directed.

TROUBLE SHOOTING

No Drive in Any Range; Cannot Load Engine

- Low oil level.
- Clogged oil suction screen.
- Defective pressure regulator valve.
- Front pump defective.
- Input shaft broken.
- Front pump priming valve stuck.

Engine Speed Flares on Standstill Starts but Acceleration Lags

- Low oil level.
- Clogged oil suction screen.
- Improper band adjustment.
- Servo apply passage blocked.
- Servo piston ring broken or leaking.
- Band facing worn.
- Low band apply linkage disengaged or broken.
- Converter stator not holding (rare).

Engine Speed Flares on Upshifts

- Low oil level.
- Improper band adjustment.
- Clogged oil suction screen.
- High clutch partially applied (blocked feed orifice).
- High clutch plates worn.
- High clutch seals leak.
- High clutch piston hung up.
- High clutch drum relief ball not seating.
- Vacuum modulator line plugged.

No Upshift

- Stuck low-drive valve.
- Defective governor.
- No rear pump output caused by stuck priming valve, sheared drive pin or defective pump.
- Throttle valve stuck or maladjusted.
- Maladjusted manual valve lever.

Harsh Upshifts

- Incorrect carburetor-to-transmission TV rod adjustment.
- Improper low band adjustment.
- Vacuum modulator line broken or disconnected.
- Vacuum modulator diaphragm leaks.
- Vacuum modulator valve stuck.
- Hydraulic modulator valve stuck.

Harsh Closed Throttle Downshifts

- Improper low band adjustment.
- High engine idle speed.
- Downshift timing valve malfunction.
- Vacuum modulator line broken or disconnected.
- Modulator diaphragm ruptured.
- Sticking pressure regulator booster valve, pressure regulator valve or vacuum modulator valve.

No Downshift

- Sticking low-drive shift valve.
- Low-drive shift plug stuck.
- High governor pressure.
- Low TV pressure.

Clutch Failure

- Low band adjusting screw backed off more than specified.
- Improper order of clutch plate assembly.
- Extended operation with low oil level.
- Clutch drum relief ball stuck.
- Abnormally high speed upshift due to improper governor action or transmission operated at high speed in manual "Low".

Car Creeps in Neutral

- Incorrect manual valve lever adjustment.
- High clutch or low band not released.

No Drive in Reverse

- Incorrect manual valve lever adjustment.
- Reverse clutch piston stuck.
- Reverse clutch plates worn out.
- Reverse clutch leaking excessively.
- Blocked reverse clutch apply orifice.

Improper Shaft Points

- Incorrectly adjusted carburetor-to-transmission linkage.
- Incorrectly adjusted throttle valve.
- Defective governor.
- Rear pump priming valve stuck.

Unable to Push Start

- Rear pump drive gear not engaged with drive pin on output shaft.
- Drive pin sheared off.
- Rear pump priming valve not sealing.

Delco-Remy "Delcotron" System

DESCRIPTION

In these alternators, Figs. 1 and 2, the rotor is mounted on ball bearings located in each end frame, and consists of multi-segmented north and south poles strengthened by field windings wound concentric with the rotor shaft. The field windings are energized by two brushes riding on slip rings pressed on the rotor shaft.

The stator windings are assembled on the inside of a laminated core that forms the Delcotron frame. Six rectifier diodes are mounted into two heat sinks located in the slip ring end frame. The diodes change the A.C. voltage to D.C. voltage which appears at the output terminal of the Delcotron.

TESTING SYSTEM IN VEHICLE

Output Test

With ammeter and voltmeter hooked-up as shown in Fig. 3, slowly increase alternator speed and check rated output as given in Specifications Chart.

Caution: Load the battery with a carbon pile rheostat or turn on all lights and accessories to prevent high voltage. Do not allow alternator to exceed recommended voltage setting of regulator.

If alternator does not provide rated output, it should be removed for service as given further on.

Indicator Light & Relay Test

Turn on ignition switch, but do not start engine. If light does not come on, check for burned out bulb.

If the light comes on and continues to glow with the alternator operating at moderate speed, check the voltage from the regulator "R" terminal to ground with the alternator in operation, Fig. 4. If the reading is more than 5 volts, the indicator relay is defective. If the reading is 5 volts or less, trouble elsewhere in the system is indicated.

Undercharged Battery

An undercharged battery condition may be caused by one or more of the following factors:

1. Loose alternator drive belt.
2. Defective battery.
3. Malfunction of field relay. To check the field relay, connect a voltmeter from regulator "F" terminal to ground, Fig. 5. Turn on ignition switch but do not start engine. The voltmeter should read battery voltage. If it reads zero volts, the field relay contacts are not closed and the relay requires further attention.
4. Excessive circuit resistance. To check for this condition, connect a voltmeter from the insulated battery post to the field terminal on the alternator, Fig. 6. Turn on ignition switch but do not start engine. *Note: If alternator field terminal is not accessible, connect to regulator "F" terminal.*
   a. If reading exceeds 0.3 volts, excessive line resistance is indicated. Clean and tighten all connections at and between battery insulated post and regulator "V" terminal, and at regulator "F" terminal and alternator field terminal.
   b. If voltage reading still exceeds 0.3 volts, clean the alternator "Bat" terminal, field relay contacts and voltage regulator contacts.
   c. If the voltage reading still exceeds 0.3 volts, check the alternator for shorted or grounded fields. Remove lead from alternator field terminal and connect an ammeter in series with the field winding.
5. Defective alternator. Check output of alternator as outlinde above.
6. Low voltage regulator setting. If no circuit defects are found, yet the battery remains undercharged, the cause most likely is a low voltage setting. Refer to "Tailoring the Voltage Setting".

Overcharged Battery

An overcharged battery may be caused by one or more of the following conditions:

1. Shorted battery cell.
2. Excessive circuit resistance. Check for this condition as covered under "Undercharged Battery".
3. High voltage regulator setting. If no circuit defects are found, yet the battery remains overcharged, refer to "Tailoring the Voltage Setting".

1117765	24	62	4.1–4.5	9000567	.014	.027	5.0–9.5	.075	—	②	—	—	—

①—Voltage setting at: 85°—13.8 to 14.6, 105°—13.7 to 14.5, 125°—13.5 to 14.3, 145°—13.4 to 14.2, 165°—13.2 to 14.1, 185°—13.1 to 13.9, 205°—13.0 to 13.8.

②—Voltage setting at: 85°—13.7 to 14.3, 105°—13.5 to 14.1, 125°—13.3 to 13.9, 145°—13.2 to 13.8, 165°—13.0 to 13.6.

Voltage Setting

The voltage at which the regulator operates varies with changes in regulator ambient temperature (temperature of air ¼" from regulator cover). To check and adjust voltage setting, proceed as follows:

1. Make connections to system as shown in Fig. 7. The ¼ ohm resistor shown will limit the alternator output to 10 amperes or less which is required when checking and adjusting voltage setting.
2. Turn the variable resistor shown to the "no resistance" position.
3. Operate the alternator for 15 minutes at approximately 3000 rpm so that the regulator is operating on the upper set of contacts. *Leave cover on regulator to establish operating temperature.*
4. After the 15 minute warm-up period, cycle the alternator (turn off ignition and stop alternator.) Disconnect jumper lead from "V" to "Bat" terminals. *Caution: Turning the field rheostat connected at regulator "F" terminal will not cycle the alternator—leave rheostat in closed position.*
5. Reconnect jumper lead. Again run alternator at approximately 3000 rpm and note voltage reading (see Specifications Chart).
6. To Adjust voltage while operating on the upper set of contacts, turn adjusting screw as shown in Fig. 8. *Caution: Always make final setting by turning screw clockwise. This insures that the spring holder will be against the screw head. After turning screw counterclockwise, pry holder up against screw head, then turn clockwise to make setting.*
7. After making setting, re-cycle the alternator. Then again operate alternator at about 3000 rpm and note voltage setting; readjust if necessary. *Note: Always cycle alternator before taking final voltage reading.*
8. After setting the voltage while operating on the upper set of contacts, check the setting while operating on the lower set of contacts as follows:
   a. Slowly increase the resistance of the variable resistor with the engine operating at 3000 rpm until the regulator begins to operate on the lower set of contacts. Note voltage reading and compare to those given in Specifications Chart. *Note: Turning the variable resistor does not cause the regulator to operate on the lower set of contacts. Return the variable resistor to the "no resistance" position. Turn the carbon pile to slightly load the battery, and adjust the variable resistor to cause the regulator to operate on the lower set of contacts. Usually, turning on the headlights will substitute for the carbon pile.*
9. The difference in voltage between the operation of the upper contacts and the lower set is increased by slightly increasing the air gap between the armature and center of core; voltage may be decreased by slightly decreasing the air gap. *Note: This setting may be made while the regulator is operating. It will be necessary to recheck the voltage setting of both contact sets if the air gap is changed.*

Fig. 3 Checking 5.5" alternator output

Fig. 4 Checking indicator light relay

Fig. 5 Checking field relay

Fig. 6 Checking circuit resistance

Fig. 7 Checking voltage setting

Fig. 9 Checking field relay closing voltage

Fig. 8 Adjusting voltage setting

Tailoring The Voltage Setting

It is important to remember that voltage setting for one set of operating conditions may not be satisfactory for a different type of operating condition. Underhood temperature, operating speeds, and night time service are all factors which affect the proper voltage setting. The proper setting is obtained when the battery remains fully charged with a minimum use of water.

If no circuit defects are found, yet the battery remains undercharged, raise the setting by 0.3 volt. Then check the battery over a period of time to see if improvements were achieved. Reset regulator if necessary.

Field Relay Unit

1. To check the closing voltage of the field relay unit, make connections as shown in Fig. 9, using a 50-75 ohm variable resistor.
2. Turn resistor to open (maximum resistance) position.
3. Turn on ignition switch. *If oil pressure switch is used, temporarily place a jumper wire across terminals.*
4. Slowly decrease resistance and note closing voltage of relay. Adjust by bending heel iron as shown in Fig. 10.

Indicator Light Relay Unit

1. To check the opening voltage of the indicator light relay, connect a 50-75 ohm variable resistor between the regulator "V" and "R" terminals.
2. Turn resistor to open (maximum resistance) position.
3. Connect a voltmeter from the regulator "R" terminal to ground (see Fig. 4).

Fig. 10 Adjusting field relay unit

4. Slowly decrease resistance and note the opening voltage. Adjust by bending heel iron as shown in Fig. 10.

BENCH TESTS

The operations described below are for both types of alternators, Figs. 11 and 12. Where important differences in test-

Fig. 11 Aluminum Delcotron (5.5")

Fig. 12 Perforated Stator Delcotron (6.2")

ing are encountered, separate mention will be made of the two alternators. Remove and disassemble the alternator as outlined later on. Then proceed with the tests as follows:

Testing Rotor

The rotor may be tested electrically with a 110-volt test lamp or with an ohmmeter.

To check for grounds, connect test lamp or ohmmeter from either slip ring to the rotor shaft or to the rotor poles. If the lamp lights or if the ohmmeter reading is low, the field windings are grounded, Fig. 13.

To check for open circuits, connect the test lamp or ohmmeter to each slip ring. If the lamp fails to light or if the ohmmeter reading is high, the windings are open.

For short circuits, the windings are checked by connecting a battery and ammeter in series with the two slip rings. An ammeter reading above 1.5 amperes indicates shorted windings. An alternate method is to check the resistance of the field by connecting an ohmmeter to the two slip rings, Fig. 13. If resistance is below 6 ohms the winding is shorted.

Testing Stator

To test for grounds, connect a 110-volt test lamp or an ohmmeter from any stator lead to the stator frame. If test lamp lights or if ohmmeter reads low, the windings are grounded, Figs. 14 and 15.

To test for open circuits, if lamp fails to light or if ohmmeter reads high when successively connected between each pair of stator leads, the windings are open, Figs. 14 and 15.

A short in the stator windings is difficult to locate without special test equipment due to the low resistance of the windings. However, if all other electrical checks are normal and the alternator fails to supply rated output, shorted stator windings are indicated.

Fig. 13 Checking rotor for grounds and open circuits

Fig. 14 Checking 6.2" stator for grounds and opens

Fig. 18 Cutting diode connectors (5.5" Delcotron)

Fig. 19 Typical tools for removing and installing diodes

Testing Diode Rectifiers

An ohmmeter or a 12-volt test lamp may be used to check diodes for shorts or opens. *Caution: Do not use a 110-volt test lamp to test diodes.*

Ohmmeter Method

1. Use an ohmmeter with a 1½ volt cell and use the lowest range scale.
2. With the stator disconnected, check a diode in the heat sink by connecting one of the ohmmeter leads to the heat sink and the other lead to the diode lead and note the reading, Figs. 16 and 17.
3. Reverse the ohmmeter leads and note the reading.
4. If both readings are very low, or if both readings are very high, the diode is defective. *A good diode will give one low reading and one high reading.*
5. Check the other two diodes in the heat sink in the same manner.
6. To check a diode mounted in the end frame, connect one of the ohmmeter leads to the end frame and the other lead to the diode lead, Figs. 16 and 17.
7. Note the reading. Then reverse the ohmmeter lead connections and note the reading. Interpret readings as mentioned in Step 4.

Test Lamp Method—Check as above with a 12-volt test lamp. When checking a diode, the lamp will light in only one of the diode checks. If lamp lights when checked in both directions, the diode is defective.

DELCOTRON REPAIRS

Service operations described below are for both type alternators. Where important differences are encountered, separate mention will be made of the two alternators.

Removal

Caution: Disconnect battery ground strap to prevent accidentally reversing the polarity of the system and damaging the diode rectifiers.

1. Disconnect "Bat", "Relay" and "Grd" leads from alternator terminals, and harness connector from field terminals at brush holder.
2. Remove alternator brace bolt, detach fan belt and lower alternator.
3. Remove bracket bolt or bolts and remove alternator from vehicle.

Disassembly

1. Remove through bolts and separate drive end frame and rotor assembly by prying apart at stator slot. Note that the separation is to be made between the stator frame and drive end frame.
2. After disassembling, place a piece of tape over the slip ring end frame bearing to prevent entry of dirt. *Caution: Brushes may drop onto rotor shaft and become contaminated with bearing lubricant. Clean brushes prior to installation with a non-toxic cleaner.*
3. Separate rotor from drive end frame.
4. Remove drive end frame bearing by removing retainer plate screws and separating retainer plate from end frame.
5. Remove slip ring brush holder from end frame.
6. Separate stator assembly and end frame by first cutting three diode connectors just below the crimp mark, Fig. 18. If the connectors are full of solder, melt the solder and then remove connectors with pliers. Cut diode leads as close as possible on the 6.2" Delcotron. Separate stator frame from end frame. *Note: On the 6.2" Delcotron, note carefully the stator lead locations, and the location of the heat sinks with respect to the end frame locating notch on the shell. Also note carefully the proper position of the output terminal and the insulating washers used on the heat sink. Caution: Do not move diode stems excessively or internal damage to diode may result.*

Inspection

1. Wash all metal parts except stator and rotor assemblies.
2. Clean and inspect bearings.
3. Inspect rotor slip rings. They may be cleaned with 400 grain polishing cloth. Rotate rotor for this operation to prevent creating flat spots on slip rings.
4. Slip rings that are out of round may be trued in a lathe to .001" maximum indicator reading. Remove only enough material to make the rings smooth and concentric. Finish with 400 grain polishing cloth and blow dry.
5. Perform bench tests of units as already described.

Diodes, Replace

In order to avoid damage to the heat sink and the diode being installed, it is recommended that the tools shown in Fig. 19 be used when replacing diodes. These tools are available from various suppliers, among which are the Kent-Moore Organization, Inc., Warren, Mich.

Negative case diodes have black markings on the case, and positive case diodes have red markings on the case. Inspect the diodes for color markings, Fig. 20, and note that the heat sink connected to the

Fig. 20 Removing and installing diodes

Fig. 21 Installing brushes (5.5" Delcotron)

alternator output terminal is insulated from the shell, and the other heat sink is grounded to the shell.

1. Support end frame with proper tool (see Fig. 19) and press diode out in an arbor press. *Do not strike diode as shock may damage other diodes.*
2. Support outside of end frame around diode hole on a flat, smooth surface and press diode into position with the proper supporting tool in an arbor press. Make sure diode is square with end frame and started straight. *Caution: Avoid moving or bending diode stem as excessive movement can cause internal damage and result in diode failure.*

Brushes, Replace

After removing brush holder, inspect brushes for wear. If they are worn halfway, they should be replaced. Inspect brush springs for discoloration or weakening. If brushes appear satisfactory and move freely in brush holder, springs may be re-used.

5.5" Delcotron

1. Remove heat sink.
2. Attach brush holder to end frame and insert pin or wire through hole, Fig. 21, to hold brushes in holder.
3. After unit has been completely assembled, withdraw pin or wire to allow brushes to drop down onto slip rings.
4. Replace heat sink, following carefully the proper stack-up of parts.

6.2" Delcotron

1. Remove brush holder and capacitor from slip ring end frame.
2. Install new brushes by pushing brushes up into holder and looping the brush leads over the catcher to keep the brushes in the holder.
3. Attach the assembly to the end frame and lift the brush leads off the catcher to allow brushes to ride on the slip rings.

Delcotron, Assemble

1. Install stator in slip ring end frame and locate connectors over relay, diode and stator leads.
2. Crimp leads with pliers only tight enough to hold connector onto leads. This will permit removal of connector later on if necessary.
3. Fill connectors with rosin core 60% tin 40% lead solder. *Caution: Do not use excessive heat for this operation, and carefully inspect to make sure no solder has run down onto diode.*
4. Position rotor and drive end frame into slip ring end frame and stator. Install and tighten through bolts.
5. Install brush holder on slip ring end frame, where necessary.

DOUBLE CONTACT REGULATORS

Figs. 22 and 23 illustrate the two types of voltage regulators commonly used with "Delcotron" alternators. While most regulator adjustments are made on the vehicle as outlined under Testing System In Vehicle, the regulator must be removed for point cleaning and air gap adjustment.

Fig. 22 Three unit double contact regulator used on vehicles having an indicator light instead of an ammeter

To remove the regulator, disconnect the leads at the regulator terminals and remove the screws securing the unit to the vehicle. *Caution: Disconnect battery ground terminal to prevent accidently grounding leads from regulator and causing damage to the diode rectifiers.*

Electrical settings must be checked and adjusted after making the mechanical adjustments described below. Before installing regulator cover, make sure rubber gasket is in place on regulator base.

The contacts on the voltage regulator unit are of a soft material and must not be cleaned with a file. They may be cleaned with crocus cloth or other fine abrasive material, and should then be washed with a non-toxic solvent to remove any residue. To clean field relay and indicator light relay contacts, use a thin, fine-cut, flat file. Remove only enough material to clean the points. *Never use emery cloth or sandpaper to clean contact points.*

Voltage Regulator Unit

Point Opening—With lower contacts touching, measure point opening between upper contacts as shown in Fig. 24. Adjust by bending upper contact arm.

Air Gap—Measure air gap between armature and core with lower contacts touching, Fig. 25. To adjust, loosen contact support bracket screw about ⅛ to ¼ turn. Place screwdriver in slot in contact support bracket and into the molded insulator (see Fig. 28). Raise screwdriver handle to increase the air gap and lower the handle to lower air gap.

Field Relay Unit

Point Opening—Point opening is checked as illustrated in Fig. 26. If adjustment is required, carefully bend flat contact support spring.

Air Gap—Check the air gap with the points just touching, Fig. 27. If the point opening and closing voltages are within specifications, the relay will operate satisfactorily even though the air gap may not be exactly according to specifications. Normally, the air gap need not be adjusted.

Fig. 23 Two unit double contact regulator used on vehicles having an ammeter instead of an indicator light

Fig. 24 Adjusting voltage regulator point opening

Fig. 25 Adjusting voltage regulator air gap

Fig. 26 Checking field relay point opening

Fig. 27 Checking field relay air gap

Fig. 28 Adjusting indicator light relay air gap

Indicator Light Relay Unit

Air gap is the only mechanical adjustment required on this unit. Hold the armature down against a gauge of the specified thickness. The contacts should barely touch. If they do not, adjust by bending upper contact support, Fig. 28.

Regulator, Install

1. Make sure attaching area is clean for proper ground, then install regulator and tighten mounting screws. *Caution: Do not tighten screws excessively as this will destroy the cushioning effect of the rubber grommets in the mounting.*
2. Attach regulator leads to proper terminals. *Caution: Do not polarize the alternator.*
3. Connect battery ground terminal.
4. Check and adjust electrical settings as covered under Testing System In Vehicle.

Engine Section

ENGINE, REPLACE

6-170 Engine

In addition to the usual items such as radiator, hood, fuel lines, electrical wiring and linkage, it is necessary to perform the following operations:

1. Remove starter and dust seal.
2. If so equipped, disconnect clutch pedal retracting spring, and remove clutch equalizer shaft and arm bracket from underbody rail.
3. Remove flywheel or converter housing upper retaining bolts through access holes in underbody.
4. Disconnect exhaust pipe at manifold.
5. Disconnect engine right and left mount at underbody bracket.
6. Remove flywheel or converter housing cover.
7. On standard transmission models, remove flywheel housing lower retaining bolts.
8. On automatic transmission cars, disconnect converter from flywheel. Remove converter housing lower retaining bolts.
9. Support transmission and flywheel or converter housing with a jack.
10. Attach engine lifting rig and raise engine out of chassis.
11. Reverse foregoing procedure when installing engine.

V8-221 Engine

In addition to the usual items such as hood, radiator, fuel lines, electrical wiring and linkage, perform the following:

1. Remove oil filter and air cleaner.
2. Disconnect transmission oil cooler lines at radiator (if equipped).
3. On automatic transmission models, disconnect throttle valve vacuum line at intake manifold. Disconnect manual shift rod at bellcrank and remove retracting spring. Disconnect transmission filler tube bracket at cylinder block.
4. If equipped with power steering, remove power steering pump and wire it out of the way and in a position that will prevent oil from spilling out. Disconnect brake vacuum line at intake manifold.
5. Remove flywheel or converter housing to engine upper bolts.
6. Remove starter and dust seal (and crankcase vent tube if so equipped).
7. Disconnect exhaust pipe at manifold, and engine support insulators at brackets on underbody.
8. If standard transmission equipped, remove remaining flywheel housing-to-engine retaining bolts. Disconnect clutch retracting spring. Remove clutch equalizer bar bracket retaining bolts and clutch release rod at release lever.
9. On automatic transmission cars, remove converter housing inspection cover. Disconnect flywheel from converter. Secure converter in housing, and remove remaining converter housing-to-engine retaining bolts.
10. Support transmission with a jack.
11. Attach an engine lifting rig.
12. Raise engine slightly and carefully pull it from transmission and lift it out of the chassis.
13. Reverse above procedure to install.

Cross sectional view of V8-221 engine

CYLINDER HEAD, REPLACE

6-170 Engine

1. Drain cooling system, remove air cleaner and disconnect battery cable at cylinder head.
2. Disconnect exhaust pipe at exhaust manifold.
3. Disconnect carburetor linkage, fuel and vacuum lines, water hoses and wires from spark plugs.
4. Remove rocker arm cover.
5. Back off valve adjusting screws to remove load from rocker arms. Then remove rocker arm shaft assembly.
6. Remove valve push rods, keeping them in proper sequence so they are returned to proper locations.
7. Remove one bolt from each end of cylinder head at opposite corners and install cylinder head guide studs ($\frac{7}{16}$"-14 x 6").
8. Remove remaining bolts and lift off cylinder head.
9. Reverse above procedure to install the cylinder head and tighten bolts in the sequence shown in Fig. 1 to the torque given in the *Engine Tightening Chart.*

Fig. 1 Cylinder head tightening sequence. 6-170 engine

V8-221 Engine

1. Remove intake manifold and carburetor as a unit.
2. Disconnect battery cable at cylinder head.
3. Remove rocker arm cover(s).
4. If equipped, remove power steering pump if left cylinder head is being removed. Wire pump out of the way and in a position that will prevent oil from spilling out.
5. Remove generator and bracket.
6. Disconnect exhaust manifolds at exhaust pipes.
7. Loosen rocker arm stud nuts so that rocker arms can be rotated to the side. Then remove push rods and keep them in order so they will be returned to their original locations.
8. Unfasten and remove head(s).
9. Reverse removal procedure and tighten head bolts in the sequence shown in Fig. 2 and to the torque listed in the *Engine Tightening Table.*

Fig. 2 Cylinder head tightening sequence. V8-221 engine

V8-221 Left Head . . . . . .E-I-E-I-E-I-E-I

VALVES, ADJUST

6-170 Engine

Before the final valve lash adjustment is made, operate the engine for 30 minutes at a fast idle to stabilize engine temperatures. To set the lash accurately, use only a step-type feeler gauge. For example, to obtain the correct setting if the clearance is .016", the .015" portion of the gauge ("go") should enter but the "no go" end (.017") should not enter.

Before starting the adjustment procedure, make two chalk marks on the crankshaft pulley. Space the marks approximately 120° apart (⅓ of circumference) so that with the timing mark the pulley is divided into three equal parts. Adjust the valves for No. 1 cylinder. Repeat the procedure for the remaining valves, turning the crankshaft ⅓ turn in the direction of normal rotation while adjusting the valves in the firing order sequence of 153624.

After the engine has been warmed up to operating temperature, check the adjustment.

V8-221 Engine

With the piston at top dead center of its compression stroke, loosen the rocker arm stud nut until there is end clearance in the push rod. Then tighten the nut just to the point where all end clearance is eliminated. This may be determined by moving the push rod with the fingers as the stud nut is tightened. When the end clearance has been eliminated, tighten the stud nut the additional number of turns listed in the *Valve Specifications Table.*

Operate the engine and check for rough engine idle or noisy lifters. Valve clearance set too tight will cause rough engine idle; if set too loose, noisy lifters will result.

If an adjustment is necessary because of the foregoing conditions, apply pressure on the push rod slowly to bleed down the valve lifter until the plunger is completely bottomed. While holding the lifter in the fully collapsed position, check the available clearance between rocker arm and valve stem tip. If clearance is not within specifications, turn the rocker arm stud nut clockwise to decrease the clearance and counterclockwise to increase clearance. *Normally, one turn of the rocker arm stud nut will vary the clearance by .066". With lifter collapsed, the clearance should be .082-.152".*

VALVES REMOVE

After taking off the head as outlined previously, proceed as follows:

1. Remove capscrews retaining rocker shaft brackets to head and remove shaft assembly (6-170).
2. Clean carbon out of combustion chambers before removing valves.
3. Compress valve springs with a suitable spring compressor, remove valve stem locks and release the springs. Remove cap retainer, spring and valve. Discard intake valve seals, Fig. 3.
4. Place valves in a board with numbered holes so they can be replaced in their original positions upon reassembly.

ROCKER ARM STUD

V8-221 Engine

If necessary to replace a rocker arm stud, a rocker arm stud kit is available and contains a stud remover, Fig. 4, a stud installer, Fig. 5, and two reamers, one .003" and the other .015".

Rocker arm studs that are broken or have damaged threads may be replaced with standard studs. Loose studs in the head may be replaced with .003" or .015" oversize studs which are available for service. *The standard studs have no identification marks, whereas the .003" oversize stud has a groove around the pilot end of the stud. The .015" oversize stud has a step produced by the increased diameter of the stud approximately $1\frac{5}{32}$" from the pilot end.*

When going from a standard size stud to a .015" oversize stud, always use a .003" reamer before finish reaming with a .015" reamer.

If a stud is broken off flush with the stud boss, use an easy-out to remove the broken stud, following the instructions of the tool manufacturer.

VALVE GUIDES

Excessive valve stem-to-guide clearance will cause lack of power, rough idling and noisy valves, and may cause valve breakage. Insufficient clearance will result in noisy and sticky functioning of valves and disturb engine smoothness of operation.

Valve stem-to-guide clearances are listed in the *Engine Valve Specifications* table. By using a micrometer and a

Cross sectional view of 6-170 engine

Fig. 3 Valve assembly for 6-170 engine. V8-221 engine is the same except the sleeve shown is not used

suitable telescope hole gauge, check the diameter of the valve stem in three places (top, center and bottom). Insert telescope hole gauge in valve guide bore, measuring at the center. Subtract the highest reading of valve stem diameter from valve guide bore center diameter to obtain valve-to-guide clearance. If clearance is not within specified limits, use the next oversize valve and ream bore to fit. Valves with oversize stems are available in .003", .015" and .030".

VALVE SPRING TESTING

Wash all springs with gasoline or other suitable solvent. Examine the springs for damage or corrosion due to acid etching, which will develop into surface cracks and cause spring failure.

Check the valve spring tension on a spring testing fixture, if one is available, Fig. 6, and according to the specifications given in the *Valve Data* chart. If a fixture is not available, at least check the free length of each spring by standing it alongside a new spring. Any spring that does not conform to the pressure specifications within 10% should be replaced. Likewise, any spring that stands shorter than the new spring used for comparison should be discarded. Of course, cocked springs should also be scrapped.

Engine lubrication diagram. V8-221 engine

Fig. 4 Rocker arm stud removal. V8-221 engine

VALVE SPRING INSTALLED HEIGHT

When valves and seats are reground the position of the valve in the head is changed so as to lessen the valve spring tension. Without proper valve spring tension the valve does not seat long enough or it may not seat completely. Since the valve is cooled by transferring heat from the valve head to the seat and thence to the coolant, improper valve spring tension will cause worn, pitted and distorted valves which result in loss of compression and power as well as poor gasoline mileage.

When valves, springs, retainers and locks are installed, measure the assembled height of the valve springs from the surface of the cylinder head spring pad to the underside of the spring retainer as shown in Fig. 7. If the assembled height is greater than the dimension given in the *Valve Specifications Chart,* install a spacer or shim of proper thickness between cylinder head spring pad and spring to bring the assembled height to specifications.

Do not install spacers unless necessary. Excessive use of spacers will result in overstressing valve springs and overloading camshaft lobes which could lead to spring breakage and worn camshaft lobes.

Fig. 5 Rocker arm stud installation. V8-221 engine

GRINDING VALVE STEMS

For Proper Lifter Clearance

If a valve grind job is needed, and if shims are found under the valve springs, very likely the valves, if reground, would not leave sufficient margin on the valve head for satisfactory operation. Since the maximum thickness of shimming that can be used satisfactorily is 1/16", and since the acceptable valve

Fig. 6 Checking valve spring pressure

Fig. 8 Rocker arm shaft assembly. 6-170 engine

head margin is approximately $\frac{3}{64}$" to $\frac{5}{64}$", one can readily see that there would be insufficient margin left on the valve head if it was reground. Therefore, it is recommended that new valves be installed.

After grinding the valves, if shims are required to restore the correct valve spring installed height, *the valve stem should be ground off the same amount as the thickness of shims required. This will automatically provide the proper static clearance between the hydraulic lifter and the push rod.*

VALVES GRIND

Clean the valves with a wire wheel brush, making sure that all carbon is removed from the top and bottom of the heads as well as the gum which might have accumulated on the stems.

In refacing valves, take off only the minimum of metal required to clean up the valve faces. If the outer edge of the valve becomes too thin or sharp due to excessive grinding, the valve must be replaced. In other words, the valve head margin must be at least $\frac{1}{32}$", otherwise the valve must be replaced.

Inspect the valve seats in the head for cracks, burns, pits, ridges or improper angle. During any general engine overhaul, it is advisable to reface the valve seats regardless of their condition.

ROCKER ARMS REPLACE

6-170 Engine

1. To disassemble, remove pin and spring washer from each end of rocker shaft, Fig. 8.
2. Slide rocker arms, springs and supports off the shaft, being sure to identify location of parts for reassembly.
3. If it is necessary to remove the plugs from the shaft ends, drill or pierce the plug on one end. Then use a steel rod to knock out the plug on the opposite end. Working from the open end, knock out the remaining plug.

Assemble

1. Lubricate all parts with engine oil. Apply Lubriplate to the rocker arm pads.
2. If plugs were removed from shaft ends, use a blunt tool or large diameter pin punch and install a plug (cup side out) in each end of shaft.
3. Install spring washer and pin on one end of shaft.
4. Install rocker arms, supports and springs in order shown in Fig. 8. *Be sure oil holes in shaft are facing downward.*
5. Complete the assembly by installing remaining spring washer and pin.

VALVE LIFTERS, REPLACE

6-170 Engine

When necessary to replace valve lifters, remove cylinder head and related parts as outlined previously. Then, using a magnet rod, Fig. 9, remove and install one lifter at a time to be sure they are placed in their original bores.

When installing, apply Lubriplate to each lifter foot and coat the remainder of lifter with oil before installation.

Fig. 7 Checking installed height of valve spring

V8-221 Engine

1. To remove lifters, remove intake manifold and related parts.
2. Remove rocker arm covers. Loosen rocker arm stud nuts and rotate rocker arms to the side.
3. Remove push rods in sequence so they can be installed in their original bores.

Fig. 9 Removing valve lifter with magnetic rod

4. Using a magnet rod, Fig. 9, remove the lifters and place them in a numbered rack so they can be installed in their original bores. *If the lifters are stuck in their bores by excessive varnish, etc., it may be necessary to use a plier-type tool to remove them. Rotate the lifter back and forth to loosen it from the gum or varnish.*
5. The internal parts of each lifter are matched sets. Do not intermix parts. Keep the assemblies intact until they are to be cleaned.
6. Clean and install the lifters in the bores from which they were removed. If new lifters are being installed, test for a free fit in the bore in which it is to be installed.

Servicing Lifters

The easiest method for locating a noisy valve lifter is by the use of a piece of garden hose approximately 4 feet in length. Place the end of the hose near the end of each intake and exhaust valve

with the other end of the hose near the ear. In this manner, the sound is localized, making it easy to determine which lifter is at fault.

Another method is to place a finger on the face of the valve spring retainer. If the lifter is not functioning properly, a distinct shock will be felt when the valve returns to its seat.

In most cases where noise exists in one or more lifters, all lifter units should be removed and cleaned. If dirt, varnish, carbon, etc. is found to exist in one unit, it more than likely exists in all the units.

Plungers are not interchangeable as they are selectively fitted at the factory. Should a plunger or lifter body become damaged, it is necessary to replace the entire unit, Fig. 10.

The plunger must be free in the lifter body. A simple test for this is to be sure the plunger will drop of its own weight in the body. There must be no excessive leakdown and there must be no ball check valve leakage.

Fig. 10 Hydraulic valve lifter. V8-221 engine

TIMING CASE COVER

6-170 Engine

1. Drain cooling system and crankcase.
2. Remove radiator, fan and pulley.
3. Use puller to remove damper.
4. Remove front cover and gasket (crankcase ventilation tube bracket is retained by one cover bolt).
5. Remove crankshaft oil slinger.
6. Drive seal out of cover with a pin punch and clean out recess in cover.
7. Coat a new seal with grease and drive it in until fully seated in recess. Check seal after installation to be sure spring is properly positioned in seal.
8. Reverse removal procedure to install cover.

V8-221 Engine

1. To remove cover, drain cooling system and crankcase. Remove air cleaner and disconnect battery ground cable.
2. Remove water hose as necessary.
3. Remove generator support bolt at water pump, and loosen generator mounting bolts.
4. Remove fan, spacer and pulley.
5. Remove power steering drive belt (if equipped). If air conditioned, remove compressor drive belt.
6. Remove crankshaft pulley and adapter.
7. Remove fuel pump and lay it to one side with flexible fuel line attached.
8. Remove oil level dipstick tube bracket and oil filler tube bracket.
9. Remove oil pan-to-front cover bolts.
10. Remove cover and water pump as an assembly.
11. Drive out cover seal with a pin punch. Clean out recess in cover.
12. Coat a new seal with grease and drive seal in until it is fully seated in recess. Check seal after installation to be sure spring is properly positioned in seal.
13. Reverse removal procedure to install cover.

Fig. 11 Timing marks lined up for correct valve timing. 6-170 engine

TIMING CHAIN

After removing the cover as outlined above, remove the crankshaft front oil slinger. Crank the engine until the timing marks are aligned as shown in Figs. 11 and 12. Remove camshaft sprocket retaining bolt and washer. Slide both sprockets and chain forward and remove them as an assembly.

Reverse the order of the foregoing procedure to install the chain and sprockets, being sure the timing marks are aligned.

CAMSHAFT REPLACE

To remove camshaft, remove cylinder head and related parts, radiator, oil pan, distributor, timing chain cover and valve lifters.

Remove timing chain and sprockets, camshaft thrust plate, and pull camshaft out of engine. If thrust plate shows signs of wear, install a new one, Figs. 13, 14.

PISTONS & RODS REMOVE

After removing the cylinder head and oil pan, use a ridge reamer to remove any ridge that may have formed on the cylinder wall at the top of the piston ring travel. Cutting the ridge before the piston is removed will avoid damaging rings or cracking ring lands of pistons during removal.

Remove the connecting rod cap and push the piston and rod out through the top of the bore. Use care to prevent the rod from nicking crankshaft journals. Identify the connecting rods (original rods are marked) when removing them so they may be installed in their original cylinder.

PISTON & ROD ASSEMBLE

When installed, piston and rod assembly should have the notch in piston head toward front of engine with oil squirt hole in rod positioned as shown in Figs. 15 and 16.

PISTONS

Pistons are available for service replacement in standard sizes and oversizes of .020", .030", .040" and .060".

If the pistons are to be re-used with new rings, remove the carbon from the ring grooves. A special tool is available for this work but a satisfactory job can be done by breaking an oil piston ring. File the broken end to a sharp, square edge and use is to scrape out the carbon. Soak the piston in cleaning solvent to loosen any carbon residue. Clean out the loosened carbon, being careful not to cut away any piston material. Clean out the oil return holes with a drill just large enough to fill the holes. Hold the drill in a tap wrench and make sure the drill does not remove any metal from the piston.

Fig. 12 Timing marks lined up for correct valve timing. V8-221 engine

Rinse the piston in solvent and wipe off the carbon on the sides of the piston. *Never use a wire brush to clean a piston as the brush will round off the edges of the ring lands.* Pistons showing scuffed or scored skirts should be discarded for new ones. Examine the ring lands carefully for cracks. If in the least bit doubtful, the piston should be scrapped.

New pistons should be fitted according to the recommendations given in Fig. 17.

Fig. 13 Camshaft and related parts. 6-170 engine

Fig. 14 Camshaft and related parts. V8-221 engine

PISTON PINS

When fitting pins, apply a light coat of engine oil to all parts. Assemble the piston to the connecting rod as shown in Figs. 15 and 16. Start the piston pin in the piston and connecting rod. Use the equipment shown in Fig. 18 and draw the pin through the piston and rod until end of pin seats in Detail 2, Fig. 18. If this equipment is not available, the pin may be installed with a suitable press.

PISTON RINGS

New rings should be assembled on the piston according to the instructions furnished by the ring manufacturer. Always use standard size rings in cylinder bores that are *standard at the bottom, regardless of the amount of cylinder wear.*

When new rings are installed without reboring cylinders the glazed cylinder walls should be slightly dulled, but without increasing the bore diameter. This is done with a "Glaze-buster" or with a hone equipped with the finest grade of stones.

New rings must be checked for clearance in piston grooves and for gap in cylinder bores. Cylinder bores and piston grooves must be clean, dry and free of carbon and burrs.

Check the clearance of each ring in its piston groove by installing the ring and then inserting feeler gauges *under* the ring. Any wear that occurs in the piston groove forms a step or ridge at the inner portion of the lower land. If gauges are inserted above the ring, the ring may rest on the step instead of on the worn portion of the lower land, and a false measurement of clearance will result.

If the piston grooves are worn to the extent that relatively high steps or ridges exist on the lower lands, the piston should be replaced because the steps will interfere with the operation of the new rings and the ring clearances will be excessive. Piston rings are not furnished in oversize widths to compensate for ring groove wear.

To check the end gap of rings, place the ring in the cylinder in which it will be used. Square it in bore by tapping with the lower end of the piston. Then measure the gap with feeler gauges. If necessary to increase the gap, file the ends of the rings carefully with a smooth file.

Fig. 15 Piston and rod assembly. 6-170 engine

ROD BEARINGS

These bearings are of the insert type, selectively fitted, and available for service replacement in standard and undersizes for use on crankshaft journals that have been reground.

If inspection reveals badly worn or scored bearings, they should be replaced. Bearings may be removed by simply taking off the bearing caps and slipping the old ones out and the new ones in. The installation of new bearings must be closely checked to maintain the proper clearance between the crankshaft and bearing surface. A convenient and accurate method for checking bearing clearance is with the use of Plastigage, which is available at any auto parts jobber.

Place the string-like plastic material so it extends the full width of the bearing, Fig. 19. Install the bearing and cap and tighten the nuts to the recommended torque which is listed in the *Engine Torque Specifications* chart. Then loosen the nuts and carefully remove the cap and bearing. The widest portion of the Plastigage is then measured with the scale on the Plastigage envelope. The graduation on the envelope corresponding to the thickness of the Plastigage gives the bearing clearance in thousandths of an inch.

MAIN BEARINGS

Caution—Main bearing clearance can be checked with Plastigage in the same manner described for rod bearings. If bearings are measured with the engine in the chassis, the crankshaft must be supported in order to take up clearance between the upper bearing insert and crankshaft journal. This can be done by tightening bearing caps of adjacent bearings with .005" to .015" cardboard, (such as a calling card) between lower bearing shell and journal. Use extreme care when this is done to avoid unnecessary strain on the crankshaft or bearings or a false reading may be obtained. Do not rotate crankshaft while Plastigage is installed.

Fig. 16 Piston and rod assembly. V8-221 engine

Be sure to remove cardboard. To install new bearings, proceed as follows:

1. Remove bearing cap and worn lower shell, Figs. 20 and 21.
2. Rotate crankshaft in normal direction to turn upper bearing shell out of crankcase. Use a cotter pin with a flattened head or the special tool made for the purpose in the crankshaft oil hole to contact the bearing and force it out.
3. Place a new upper shell on the crankshaft journal with the locating notch in the correct position and rotate the shaft to turn the bearing in place.
4. Install the lower bearing shell in the cap.
5. Tighten all cap nuts to the torque given in the *Engine Tightening Table.*

Fig. 17 Piston clearance chart

CRANKSHAFT OIL SEAL

A braided oil seal is pressed into the upper and lower grooves behind the rear main bearing, Figs. 20 and 21. Directly in front of this seal is an oil slinger which deflects the oil back into the oil pan. Should the braided seal require replacement, the installation of the lower half is accomplished as follows:

With the bearing cap and lower bearing half removed, install a new seal so that both ends protrude above the cap. Tap the seal down into position or roll it snugly in its groove with a smooth rounded tool. Then cut off the protruding end of the seal with sharp knife or razor blade.

Installing Upper Seal

Although the usual practice is to remove the crankshaft when the upper half of the seal is to be replaced, it is possible to do the job without removing the crankshaft as follows:

To remove the old seal, use needle-nose pliers to grasp the end of the seal which is most accessible. Pull the seal downward while rotating the crankshaft slowly in the direction that the seal is being removed.

To install the new seal, fasten a length of wire or strong string such as fishing line securely to one end of the new seal. See that the point of fastening is not bulky and that it is not over ⅜" from the end of the seal. Coat the seal with Lubriplate. Pass the free end of the wire or string up over the crankshaft at the point where the seal is being installed. Then exert a firm, steady pull on the wire or string at the same time rotate the crankshaft slowly in the direction of the pull. This will help to move the seal into position. When the installation is completed, trim the ends of the seal flush with the engine block.

V8-221 Service Note

The crankshaft rear seal is in contact with the outer surface of the flywheel flange rather than on the main bearing journal. In this design, the front face of the flange is exposed to crankcase splash. Therefore, to eliminate the possibility of oil leaks through the threaded holes in the flange, the flywheel attaching capscrews must be coated with an oil resistant sealer.

OIL PAN REPLACE

6-170 Engine

1. On car with manual shift transmission, remove clutch retracting spring.
2. Remove crossmember.
3. Unfasten and pull stabilizer bar downward.
4. Remove oil pan retaining bolts and crank engine as required to gain clearance and remove pan.
5. When installing the pan, position the oil pan front seal on the timing case

Fig. 18 Piston pin installation

Fig. 19 Checking rod bearing clearance with Plastigage

cover. Be sure the tabs on seal are over the oil pan gasket. This also applies to the seal on the rear main bearing cap.

V8-221 Engine

1. Remove oil dipstick.
2. Remove crossmember.
3. Remove oil pan bolts and crank engine as required to gain clearance for pan removal.
4. When installing pan, position oil pan front seal on timing case cover. Be sure tabs on seal are over oil pan gasket. This also applies to the seal on the rear main bearing cap.

OIL PUMP REPLACE

6-170 Engine

1. Remove oil pan as directed above.
2. Remove pump pick-up tube and screen.
3. Unfasten and remove pump from engine.
4. Reverse order of removal to install.

V8-221 Engine

1. Remove oil pan as outlined above.
2. Remove pump inlet tube and screen.
3. Remove pump retaining bolts and remove pump, gasket and intermediate shaft.
4. To install, position intermediate drive shaft into distributor socket. With shaft seated in socket, stop on shaft should touch roof of crankcase. Remove shaft and position stop as necessary.
5. With new gasket on pump housing and stop properly positioned, insert intermediate shaft into oil pump. Install pump and shaft as a unit. *Do not force pump into position if it will not seat readily. The drive shaft hex may be misaligned with distributor shaft. To align, rotate shaft into new position.*

Fig. 20 Crankshaft and related parts. 6-170 engine

Fig. 23 Oil pump assembly. V8-221 engine

OIL PUMP REPAIRS

Referring to Figs. 22 and 23, disassemble pump. To remove the oil pressure relief valve, insert a self-threading sheet metal screw of the proper diameter into the oil pressure relief valve chamber cap and pull cap out of chamber. Remove spring and plunger.

The inner rotor and shaft and the outer race are serviced as an assembly. One part should not be replaced without replacing the other.

Install the pump cover and tighten to 6-9 ft. lbs. torque.

Fig. 22 Oil pump assembly. 6-170 engine

Fig. 21 Crankshaft and related parts. V8-221 engine

RADIATOR

On cars with automatic transmission, disconnect oil cooler lines at radiator. Remove radiator retaining bolts and lift out radiator.

If air conditioned, unfasten fan shroud from radiator. Then unfasten and remove radiator, and lift out fan shroud.

WATER PUMP REPLACE

Drain cooling system and disconnect radiator lower hose and heater hose at water pump. Remove drive belt, fan and pulley (also spacer on V8-221). Unfasten and remove pump.

WATER PUMP REPAIRS

To disassemble pump, remove hub from impeller shaft. Press shaft and bearing out of housing. Remove impeller from shaft.

To assemble, clean all gasket material from pump. If a new shaft is used, install the slinger on the shaft in the same relative position as the old slinger. Coat the bearing outer diameter with grease and press the shaft into the housing. Apply a light film of waterproof sealer on a new seal and press seal into housing. Install impeller. Lightly coat seal rubbing face of impeller with grease, then press shaft onto impeller.

Press shaft into impeller just far enough so that pump housing lightly touches face of adapter ring. The impeller-to-pump body clearance should be .005-.025" on 6-170 engine and .030-.050" on V8-221 after impeller is installed.

Press water pump onto shaft until there is $3\frac{15}{16}$" on 6-170 engine and $5\frac{5}{32}$" on V8-221 from gasket surface to outside surface of pump hub.

DISTRIBUTOR REPLACE

1. To remove the distributor, disconnect the primary wire and vacuum control pipe.
2. Remove distributor cap.
3. Scribe a mark on the distributor body indicating the position of the rotor, and scribe another mark on the body and engine block indicating position of distributor body in block. These marks can be used as guides when installing distributor in a correctly timed engine.
4. Remove hold down screw or screws and lift distributor out of block. *Do not crank engine while distributor is removed or the initial timing operation will have to be performed.*

Fig. 24 Ignition details. V8-221 engine

Installation

If the crankshaft has not been disturbed, install the distributor, using the scribed marks previously made on the distributor body and engine block as guides.

If the crankshaft has been rotated while the distributor was removed from the engine, it will be necessary to retime the engine. Crank the engine to bring No. 1 piston on top dead center of its compression stroke. Align the timing mark on the crankshaft pulley with the timing pointer (see *Tune Up* chart). Install the distributor so that the rotor points to the No. 1 spark plug wire terminal in the distributor cap.

Make sure the oil pump intermediate shaft properly engages the distributor shaft. It may be necessary to crank the engine with the starter, after the distributor drive gear is properly engaged, in order to engage the oil pump intermediate shaft.

IGNITION TIMING

Align the distributor rotor with No. 1 spark plug wire terminal in the distributor cap, Fig. 24, when No. 1 piston is on the compression stroke and timing mark on the crankshaft pulley and pointer are aligned (see *Tune Up* chart).

With the timing mark in line with the pointer, the distributor points should just start to open. It may be necessary to rotate the distributor body clockwise slightly and then counter-clockwise until the points just start to open. Tighten the distributor lock plate screw.

Start the engine and check the timing with a timing light.

Using Timing Light

Connect the timing light wires. Clean the dirt from the timing mark and if necessary use white chalk or paint to make the mark more visible.

Start the engine and operate at idle speed. Direct the light on the timing mark. It should flash just as the timing mark lines up with the pointer, indicating correct timing. If the pointer and timing mark do not line up as the light flashes, rotate the distributor as required to bring them in alignment.

STARTER REPLACE

1. Disconnect starter cable at terminal, remove starter retaining screws and remove starter and rubber dust ring.
2. When installing, position rubber dust ring on flywheel housing so that the flared portion of the ring makes a good seal to the housing at all points.
3. Position starter to flywheel housing and start the retaining screws. On 6-170 engine with automatic transmission, the transmission dipstick tube bracket is mounted under one of the starter mounting bolts.
4. Snug all bolts, then tighten to 12-15 ft. lbs. torque; on 6-170 engine, tighten center bolt first.

Carburetor Section

Performance Complaints

Flooding, stumble on acceleration or other performance complaints are in many instances caused by the presence of dirt, water or other foreign matter in the carburetor. To aid in diagnosing the cause of the complaint, the carburetor should be carefully removed from the engine without draining the fuel from the bowl. The contents of the fuel bowl may then be examined for contamination as the carburetor is disassembled.

Check the fuel in the bowl for contamination by dirt, water, gum or other foreign matter. A magnet moved through the fuel in the bowl will pick up and identify any iron oxide dust that may have caused intake needle and seat leakage.

Inspect gasket surfaces. Small nicks or burrs should be smoothed down to eliminate air or fuel leakage. On carburetors having a vacuum piston, be especially particular when inspecting the top surface of the inner wall of the bowl around the vacuum piston passage. A poor seal at this location may contribute to "cutting-out on turns" complaint.

Fill the carburetor bowl with clean fuel before installing on manifold. This will help prevent dirt trapped in the fuel system from being dislodged by the free flow of fuel as the carburetor is primed. The operation of the floats and intake needle and seats may be checked under pressure if a fuel pump is used at the bench to fill the carburetor bowl. Operate the throttle several times and visually check the discharge of the pump jets.

Manifold Heat Control Valve

An engine equipped with a manifold heat control valve can operate with the valve stuck in either the open or closed position. Because of this an inoperative valve is frequently overlooked at vehicle lubrication or tune-up.

A stuck valve in the "heat-off" position can result in slow warm up, deposits in combustion chamber, carburetor icing, flat spots during acceleration, low gas mileage and spark plug fouling.

A valve stuck in the "heat-on" position can result in power loss, engine knocking, sticking or burned valves and spark plug burning.

To prevent the possibility of a stuck valve, check and lubricate the valve each time the vehicle is lubricated or tuned-up. Check the operation of the valve manually. To lubricate the valve, place a few drops of penetrating oil on the valve shaft where it passes through the manifold. Then move the valve up and down a few times to work in the oil. *Do not use engine oil to lubricate the valve as it will leave a residue which hampers valve operation.*

Positive Crankcase Ventilation

When there is a complaint of carburetor troubles and the car is equipped with a Positive Crankcase Ventilator Unit, it is advisable first to check the operation of this unit before servicing the carburetor. For data on this unit, see the *Tune Up Chapter*.

FORD CARBURETOR ADJUSTMENTS

★See Tune Up Chart for hot idle speed.

Year	Model	Carb. Type	Idle Adjustments★			Float Level	Fast Idle Cam	Secondary Throttle Plate	Pump Stroke	Choke Setting
			Mixture Screws Turns Open	Fast Idle Speed	Dashpot Setting					
1962	V8-221 Std. Tr.	2 Bar.	1–1½	1300①	None	21/32②	.050③	None	④	2 Lean
	V8-221 Auto. Tr.	2 Bar.	1–1½	1600①	5/64⑤	21/32②	.050③	None	④	2 Lean

FORD CARB. NOTES

①—With idle speed and mixture properly adjusted and with engine at normal operating temperature, place fast idle screw on kickdown step of cam. Then adjust screw to the R.P.M. specified.

③—Open throttle plates so that fast idle screw will not interfere with fast idle cam when bellcrank lever is rotated. Hold choke plate closed by turning choke housing shaft counterclockwise. Measure clearance between cast stop on back of choke housing and edge of fast idle cam. If clearance is not as specified, loosen bellcrank lever screw and turn lever as required.

Fig. ②—Float level measured from top surface of main body to top of free end of float with float in uppermost position.

④—The over-travel lever has four holes and pump link has two holes to control pump stroke for different engine applications. Install pump operating rod in the inside hole in pump link for all climatic conditions.

⑤—With engine at normal operating temperature and hot idle speed properly adjusted, loosen dashpot locknut. Hold throttle closed and depress plunger. Clearance between throttle lever and plunger should be as specified. To adjust, turn dashpot in its bracket as required to obtain proper clearance between tip of plunger and throttle lever. Tighten locknut.

HOLLEY CARBURETOR ADJUSTMENTS

★See Tune Up Chart for hot idle speed.

Year	Model	Carb. Type	Idle Adjustments★				Float Level	Fuel Level	Float Bowl Vent Valve	Pump Travel	Choke Unloader	Choke Setting
			Mixture Screws Turns Open	Air Bypass Turns Open	Fast Idle Speed	Dashpot Plunger Clearance						
1962	6-170 Std. Tr.	1 Bar.	1–1½	None	None	None	5/16②		None	③	None	None
	6-170 Auto. Tr.	1 Bar.	1–1½	None	None	9/64①	5/16②		None	③	None	None

HOLLEY NOTES

①—With idle speed and mixture properly adjusted, loosen lock nut and screw dashpot in or away from throttle operating lever. Hold throttle closed, then depress plunger to bottom with a screwdriver. Screw dashpot in toward throttle lever until clearance between lever and tip of plunger is as specified.

②—With air horn inverted and gasket removed, check float setting, using a drill of the size listed in table, between top of free end of float and air horn. If necessary, bend tab on float arm to obtain proper setting.

③—Pump stroke is controlled by changing position of pump link in throttle lever pump lever on throttle shaft. Hole closest to throttle shaft is for average or hot weather operation; outer hole for cold weather operation.

Clutch & Transmission Section

CLUTCH PEDAL ADJUST

Adjust the clutch pedal whenever the clutch does not disengage or engage properly, or when new clutch parts are installed. Both the total travel and free travel should be adjusted. *Improper adjustment of the clutch pedal is one of the most frequent causes of clutch failure and can be a contributing factor in some transmission failures.*

1. Disconnect interlock shift rod at equalizer bar, Fig. 1.
2. Measure total travel of pedal. If travel is not within 6⅝" to 6⅞", move clutch pedal bumper and bracket up or down as required. *Always check this adjustment before checking free travel because total travel will affect free travel adjustment.*
3. With clutch pedal against bumper (pedal released), measure distance between assist spring eye centers—which should be 10". If necessary, adjust retainer length as required, Fig. 2.
4. With engine running at normal idle speed, depress pedal just enough to take up free travel of pedal and note the amount of this travel. The difference between this measurement and the measurement when the pedal is released is the pedal free travel.
5. If the travel is not within $\frac{15}{16}$" to $1\frac{1}{16}$", adjust clutch pedal to equalizer rod. To increase free travel, loosen rearward adjusting nut and tighten forward adjusting nut. To reduce free travel, loosen forward nut and tighten rearward nut. Both nuts must be tightened against trunnion after making this adjustment.
6. With transmission in neutral and interlock snugly engaged, connect interlock shift rod.
7. As a final check on V8-221 engine, measure the free travel with the transmission in neutral and the engine running at about 3000 rpm. If free travel at this speed is not ½", readjust to obtain specified free travel.

INTERLOCK ADJUST

Be sure clutch linkage and pedal height are correctly adjusted before adjusting the interlock, Fig. 1.

1. With interlock shift rod disconnected at equalizer bar and with transmission in neutral, adjust position of interlock so that it fits snugly in the shift lever projection. Tighten interlock bolts.
2. Shift transmission into low and into neutral to check operation of interlock. Adjust length of interlock shift rod so that the low and reverse shift lever is engaged by the interlock until the clutch pedal enters the overtravel or reserve area. Readjust interlock for snug fit, if necessary.
3. With transmission in neutral, connect interlock rod and check shift linkage operation. *If interlock is properly adjusted, it is impossible to clash the low and reverse gears with the clutch pedal fully raised.*

Fig. 1 Standard transmission shift interlock mechanism

Fig. 2 Clutch mounting and linkage

CLUTCH REPLACE

1. Remove transmission as outlined further on.
2. Remove release lever retracting spring. Then slide release bearing and hub off release lever, Fig. 2.
3. Remove inspection cover on 6-170 engine and flywheel housing on either engine.
4. Loosen clutch cover attaching bolts a little at a time until spring tension is relieved. *If the same cover and pressure plate is to be installed, mark the cover and flywheel so that the pressure plate can be installed in the same position.*
5. Remove cover, pressure plate and clutch disc.
6. Remove clutch release lever from housing.
7. Reverse removal procedure to install the clutch and adjust the pedal as outlined previously.

STD. TRANS. REPLACE

1. Disconnect and slide drive shaft off transmission mainshaft.
2. Disconnect speedometer cable.
3. Disconnect gearshift and interlock rods at transmission.
4. Disconnect parking brake cable.
5. Support engine with a jack.
6. Unfasten extension housing from rear support.

Fig. 4 Manual shift transmission used with V8 engine without overdrive

Fig. 3 Manual shift transmission used with six cylinder engine

7. Raise rear of engine and remove engine rear support and frame crossmember as a unit.
8. Support transmission on a jack.
9. Unfasten transmission from flywheel housing and install guide studs in the two lower holes .
10. Move transmission and jack rearward until clutch shaft clears flywheel housing. If necessary, lower engine enough to gain clearance for transmission removal. *Do not depress clutch pedal while transmission is removed.*
11. Reverse removal procedure to install transmission and adjust shift linkage and clutch pedal.

O.D. TRANS. REPLACE

The overdrive unit cannot be removed from the car as a separate assembly. Remove the transmission and overdrive unit together, as follows:

1. Disconnect solenoid and governor wires from connectors near solenoid.
2. Remove overdrive wiring harness from clip on transmission.
3. Disconnect overdrive control cable from lever on side of unit and from clamp at solenoid.
4. Remove transmission and overdrive by following procedure outlined for standard transmission.

STD. TRANS. REPAIRS

6-170 Engine

1. Referring to Fig. 3, drain lubricant and remove cover.
2. Remove extension housing. *To prevent mainshaft from following the housing (with resultant loss of needle bearings) tap end of mainshaft with soft hammer while withdrawing housing.*
3. Remove speedometer drive gear, snap ring and drive ball from mainshaft.
4. Remove idler and countershaft retainer, tapping ends of both shafts if necessary to free retainer.
5. Using a suitable arbor, drive countershaft out of cluster gear and transmission case, leaving arbor in gear. Then lower cluster gear to bottom of case.
6. After removing bearing retainer and gasket, remove main drive gear and front synchronizer blocking ring from case.
7. Remove synchronizer snap ring from mainshaft. Then, while holding synchronizer parts together, pull mainshaft out of case. Remove mainshaft parts and two shift forks. *For reference in asembly, notice which synchronizer hub faces forward.*
8. Using a soft drift, drive reverse idler shaft out of transmission case and lift out idler gear, shaft and cluster gear out of case.

Fig. 5 Overdrive transmission used with V8 engine

9. If necessary to remove shift mechanism, first remove the shift levers. Then from the underside of the case, drive out the tapered pins that hold the cam and shaft assemblies in the case. Drive out the cam and shafts and remove the plunger.
10. Remove shift lever oil seals.
11. Remove retaining snap ring and press main drive gear shaft out of bearing and oil slinger.
12. Remove retaining snap ring and press mainshaft out of rear bearing.
13. Reverse above procedure to assemble the transmission, referring to Fig. 3.

STD. TRANS. REPAIRS

V8-221 Engine

The following describes the procedure for units without overdrive. For detailed service on the overdrive, consult the *Overdrive* chapter. To disassemble the transmission, see Figs. 4 and 5 and proceed as follows:

1. Remove gearshift housing.
2. Drive out the pin that retains the countershaft and idler gear shaft to the transmission case.
3. Unfasten the extension housing and twist it ¼ turn counterclockwise to permit removal of countershaft.
4. Drive countershaft out the rear of case, using a cluster gear roller retainer shaft tool or a spare countershaft cut to the length of the cluster gear. Leave cluster gear and dummy shaft in case until after main drive gear and mainshaft have been removed. Remove extension and mainshaft assembly from case.
5. Drive reverse idler shaft out of case and lift out reverse idler gear.
6. Unfasten and remove main drive gear bearing retainer.
7. Tap main drive gear out through front of case.
8. To disassemble mainshaft, remove snap ring that holds it to the extension housing. Tap mainshaft out of extension. Remove snap ring from in front of synchronizer and strip mainshaft of all parts.
9. After cleaning and inspecting parts, reassemble transmission by reversing the order of the foregoing procedure.

GEARSHIFT LINKAGE ADJUST

If the transmission shifts hard or will not engage, the gearshift rods may need adjustment. Move the shift lever through all shift positions to be certain that cross-over operation is smooth. If not adjust as follows:

1. With transmission in neutral, loosen lock nut on each lever.
2. Center levers in retainer at lower end of steering column. The shift handle should be approximately 10° above horizontal.
3. Tighten lever lock nuts.
4. Check shift for smooth cross-over operation. *Be sure levers do not strike the ends of retainer slots before transmission detents are engaged.*

AUTOMATIC TRANS.

For detailed repair procedure and maintenance requirements on this transmission, refer to the *Two-Speed Fordomatic section* of this manual. The following outlines the procedure for adjusting the throttle linkage.

CONTROL LINKAGE

V8-221 Engine

1. Referring to Fig. 6, apply parking brake and place selector lever at N.
2. Run engine at normal idle speed and connect tachometer to engine.
3. Carburetor throttle lever must be against idle adjusting screw at 500 rpm in D.
4. Bottom dashpot plunger against its spring and check clearance between bottomed plunger and throttle lever. If not within .060" to .090", adjust as required.
5. With engine stopped, adjust accelerator connecting link length to obtain a pedal height of $3\frac{15}{16}$", measured from top front corner of pedal to floor mat (dimension C, Fig. 6).
6. A ¼" gauge pin must freely enter gauging holes. Adjust carburetor connecting link if necessary.
7. Remove gauge pin and road test car to check downshift operation. If downshift problems exist after linkage adjustments, check for bent or sticking linkage.

6-170 Engine.

Perform Steps 1 through 5, as outlined for V8 engine, then proceed as follows:

Adjust Tinnerman nut on dowshift adjusting rod to obtain a dimension of $2\frac{5}{16}$" at "B", Fig. 6. If it must be reduced more than ¼" to obtain a kickdown shift, look for bent linkage and incorrect pedal height.

Manual Linkage Adjust

1. With engine stopped, loosen clamp at shift lever so that shift rod is free to slide in clamp.
2. Position selector lever so that pointer lines up in D position.
3. Shift manual lever at transmission into the D detent (second from rear).
4. Tighten clamp on shift rod and check pointer alignment for all selector lever detent positions.

Starter Neutral Switch

1. Check starter circuit in all selector lever positions.
2. To adjust switch, loosen mounting screws at steering column and position switch so that starter circuit is closed only when the selector lever is at N and P.

Fig. 6 Automatic transmission control linkage. Upper is for 6-170 engine, lower for V8-221 engine

Rear Axle & Brake Section

REAR AXLE

This rear axle, Fig. 1, is a banjo-housing hypoid in which the drive pinion is mounted below the centerline of the ring gear. The drive pinion is straddle-mounted in that two opposed tapered roller bearings support the pinion shaft at the front of the pinion gear and a straight roller bearing supports the pinion shaft at the rear of the pinion gear.

The pinion shaft and gear are assembled in the pinion retainer which is bolted to the carrier housing. Two carrier and differential cases are used to accommodate two bearing sizes.

Axle Shaft, Remove

Take off wheel and unfasten brake drum from axle shaft flange. Through hole provided in flange, remove nuts that secure brake support plate to axle housing. Then with suitable puller pull shaft out of housing. Use care not to dislodge the brake support plate or damage the oil seal in the housing. Install one nut to hold brake plate in position.

Axle Shaft Bearings, Replace

Axle shaft bearings should be removed only when necessary to install a new bearing. A bearing once removed should be discarded.

To replace a bearing, loosen axle shaft bearing retainer ring and remove retainer. The bearing may be removed with a bearing puller, after which remove retainer plate.

To install, place retainer plate on shaft. Press bearing up against shoulder on shaft. Install bearing retainer ring and press it firmly against bearing. Before installing shaft, examine oil seal and replace if necessary.

Oil Seal, Replace

Before installing a new oil seal it should be soaked in oil for at least 30 minutes to make it soft and pliable. When

Fig. 1 Rear axle disassembled

installing the seal, use a suitable seal driver, driving the seal into the axle housing and tight against the shoulder. When installed, check outer diameter of seal for tightness in housing to avoid possible leaks.

Axle Shaft, Install

Remove temporary nut holding brake plate, and lubricate bearing bore in housing. Clean brake plate surface and install new gaskets between retainer plate and brake plate. Slide axle shaft into housing, using care not to damage oil seal. Push shaft in until its bearing is tight against shoulder in housing. Tighten axle shaft nuts to a torque of 30-35 ft. lbs. and install brake drum and wheel.

Rear Axle, Remove

It is not necessary to remove the entire rear axle assembly to service the differential carrier assembly. After removing propeller shaft and axle shafts, unfasten the differential carrier from the axle housing and remove carrier from housing.

Rear Axle Repairs

The threaded nut type of differential bearing adjustment is used. The procedure for making this adjustment, as well as the assembly of the differential case, replacing a ring gear, checking ring gear and pinion backlash and other differential case operations, are given in the *Rear Axle Chapter*.

The following service procedure is significant for this type axle.

Disassemble Carrier

1. Mark one differential bearing cap and bearing support to ensure proper assembly. Remove adjusting nut locks, bearing caps and adjusting nuts. Lift differential out of carrier.
2. Remove drive gear from differential case.
3. Drive out differential pinion shaft retainer and separate the differential pinion shaft and remove gears and thrust washers.
4. Remove drive pinion retainer from carrier. Remove O-ring from retainer.
5. Remove pinion locating shim. Measure shim thickness with micrometer.
6. If the drive pinion pilot bearing is to be replaced, drive the pilot end and bearing retainer out at the same time. When installing, drive the bearing in until it bottoms. Install a new retainer with the concave side up.
7. Mount the drive pinion retainer assembly in a holding fixture and remove pinion shaft nut and flat washer. Then remove universal joint flange, oil seal and slinger.
8. Remove pinion retainer from fixture and place a protective sleeve or hose on the pinion pilot bearing surface. Then press the pinion shaft out of front bearing cone and remove spacer.
9. Remove pinion rear bearing cone.
10. Do not remove pinion bearing cups from retainer unless they are worn or damaged. The flange and pilot are machined by locating on these cups after they are installed in the bores. If new cups are to be installed, make sure they are seated in the retainer by trying to insert a .0015" feeler gauge between cup and bottom of bore.

Assemble Carrier

Differential Case—Place a side gear and thrust washer in the differential case bore. *Lubricate all parts liberally with axle lubricant during assembly.* With a soft-faced hammer, drive pinion shaft into case only far enough to retain a pinion thrust washer and pinion gear. Place the second pinion and thrust washer in position. Drive the pinion shaft into place. Be careful to line up pinion shaft retainer holes. Place second side gear and thrust washer in position and install differential case cover. Install retainer. A pinion or axle shaft spline can be inserted in side gear spline to check for free rotation of differential gears.

Insert two $\frac{7}{16}$" x 2" bolts through differential flange and thread them 3 or 4 turns into the drive gear as a guide in aligning the drive gear bolt holes. Press or tap the drive gear into position. Install and tighten the drive gear bolts evenly and alternately across the gear to 60-65 lb. ft. torque.

If the differential bearings have been removed, use a suitable press to install them.

Assemble Pinion

Pinion and Retainer—Install the pinion rear bearing cone on the pinion shaft and install a new spacer on the shaft. Place the bearing retainer on the pinion shaft, then install the front bearing cone. *As the bearing is pressed into position, rock the pinion retainer. Do not press the bearing on the shaft until all play is removed between retainer and bearings as the spacer may be compressed too much.*

Lubricate both bearings with axle lubricant. Place oil slinger in position. Coat the outside edge of a new oil seal with an oil-resistant sealer and press it into the bearing retainer. New seals need not be soaked before installation. Install the universal joint flange. Place the flat washer over the pinion shaft and start the pinion shaft nut.

Hold the flange and tighten the pinion shaft nut until a torque required to turn the pinion is 8-12 *inch* lbs. with used bearings or 17-27 *inch* lbs. with new bearings. As the pinion shaft nut is tightened, rotate the pinion shaft frequently to allow the bearing to seat.

Pinion, Adjust

Shim Selection—Manufacturing tolerances in the pinion bore dimensions and in the best operating position of the gears make an adjustment shim necessary. This shim is placed between the pinion retainer and the carrier, Fig. 1. An increase in the thickness of the shim moves the pinion *away* from the drive gear. Manufacturing objectives are to make axles requiring a .0015" shim and if a new assembly is being built, a .0015" shim should be used for a tentative build-up. Shims are available in .010" to .021" thicknesses in steps of .001".

Pinions and drive gears are marked, when matched, with the same number. Following the number on the pinion is a minus (—) or plus (+) followed by a number. If the pinion is marked "—1" it indicates that a shim .001" thinner than a standard shim for this carrier is required. A minus number means the pinion should be moved closer to the drive gear and a thinner shim is required. A plus number means the pinion should be moved farther from the drive gear and a thicker shim is required. A pinion marked zero (0) is a standard pinion.

To select a shim, measure the original shim with a micrometer. Note the dimensional mark on the original pinion. Compare the mark on the original pinion with the mark on the new pinion to determine how the original shim should be modified.

For example, if the original shim is .015" and the original pinion is marked "—1", the new pinion requires a +1 shim. Therefore, the new pinion requires a .002" thicker shim, and a .017" shim should be used. If the new pinion is marked the same as the old pinion, no shim change is required.

MASTER CYLINDER, REPLACE

1. Remove rubber boot from rear end of master cylinder in passenger compartment.
2. Disconnect brake line from cylinder and stop light wires from switch.
3. Unfasten master cylinder from dash panel and lift cylinder out and away from push rod. Remove boot from push rod.
4. Reverse above procedure to install and torque mounting bolts to 12-18 ft. lbs.
5. Fill reservoir to within ⅜" of the top with heavy duty brake fluid. Then bleed hydraulic system as given in the *Hydraulic Brake System* chapter.

POWER BRAKE UNIT, REPLACE

1. Working inside car below instrument panel, disconnect booster valve operating rod from brake pedal. To do this, remove eccentric shoulder bolt. Remove rubber boot from valve operating rod.
2. Open hood and disconnect wires from stop light switch at brake master cylinder.
3. Disconnect brake line at master cylinder outlet fitting.
4. Disconnect vacuum hose from booster unit.
5. Unfasten and remove booster and bracket from dash panel (4 bolts), sliding valve operating rod out from engine side of dash panel.
6. Reverse removal procedure, adjust pedal height and bleed brake system.

Front End and Steering Section

CAMBER & CASTER, ADJUST

Caster and camber can be adjusted by loosening the bolts that attach the upper suspension arm inner shaft to the underbody and moving the arm assembly in or out in the elongated bolt holes, Fig. 1. Since any movement of the arm affects both caster and camber, *both* factors should be balanced against one another when making the adjustment.

1. Install the special tool as shown in Fig. 2. *Do not install the tool from underneath the car. For easier installation, face the outside of the wheel and reach behind each end of the wheel under the fender with each half of the tool. Turn both tool adjusting screws until the tool is snug between the suspension upper arm and the lower corners of the front suspension housing, Fig. 3.*
2. Loosen upper arm inner shaft bolts 2 or 3 turns, Fig. 1. Then turn the wheels to the extreme left and right positions to free the arm.
3. Turn wheels to the straight-ahead position. Then turn the upper arm inner shaft bolts snug (not tight).

Fig. 1 Upper control arm inner shaft bolts

4. Turn tool adjusting screws to move the arms of the tool in or out and thus move the suspension in or out as required for adjustment.
   a. To move front end of suspension upper arm *out,* turn tool front screw *clockwise.*
   b. To move rear end of upper suspension arm *out,* turn tool rear screw *clockwise.*
   c. To move front end of upper suspension arm *in,* turn tool front screw *counterclockwise.*
   d. To move rear end of upper suspension arm *in,* turn tool rear screw *counterclockwise.* The relationship between turning the tool adjusting screws for upper suspension arm movement and changes in caster and camber is shown in Fig. 4.
5. After caster and camber have been adjusted to specifications, tighten the upper arm inner shaft bolts to 115-135 ft. lbs. torque. Remove tool and recheck adjustments.

TOE-IN, ADJUST

Check the steering wheel spoke position when the front wheels are in the

Fig. 2 Upper side view of caster and camber adjusting tool installation

Fig. 3 Lower left view of caster and camber adjusting tool installation

SUSPENSION UPPER ARM MOVEMENT	CASTER CHANGE	CAMBER CHANGE
Front End Out Turn Front Screw Clockwise	**Tilt Backward** Increase Positive Caster or Decrease Negative Caster	**Tilt Outward** Increase Positive Camber or Decrease Negative Camber
Rear End Out Turn Rear Screw Clockwise	**Tilt Forward** Decrease Positive Caster or Increase Negative Caster	**Tilt Outward** Increase Positive Camber or Decrease Negative Camber
Front End In Turn Front Screw Counterclockwise	**Tilt Forward** Decrease Positive Caster or Increase Negative Caster	**Tilt Inward** Decrease Positive Camber or Increase Negative Camber
Rear End In Turn Rear Screw Counterclockwise	**Tilt Backward** Increase Positive Caster or Decrease Negative Caster	**Tilt Inward** Decrease Positive Camber or Increase Negative Camber

Fig. 4 Caster and camber adjustments

Fig. 5 Tie rod adjustments for toe-in and steering wheel spoke position

Fig. 6 Toe-in and steering wheel spoke alignment adjustments

straight-ahead position. If the spokes are not in the normal position, they can be adjusted while toe-in is being adjusted.

1. Loosen clamp bolts on each tie rod end sleeve.
2. Adjust toe-in. If steering wheel spokes are in their normal position, lengthen or shorten both rods equally to obtain correct toe-in, Fig. 5. If spokes are not in normal position, make necessary rod adjustments to obtain correct toe-in and steering wheel spoke alignment, Fig. 6.

WHEEL BEARINGS ADJUST

With wheel raised off floor, pry off wheel cover and remove grease cap from hub. Wipe excess grease from end of spindle and remove cotter pin and nut lock. Then adjust bearings as shown in Fig. 7.

Fig. 7 Front wheel bearing adjustment

Fig. 8 Fairlane front suspension

CHECKING BALL JOINTS FOR WEAR

If loose ball joints are suspected, first be sure the front wheel bearings are properly adjusted and that the control arms are tight. Then check ball joints as follows:

A method of checking the friction load on the upper joints by means of a torque wrench is provided. After separating the upper joint from the steering knuckle, the joint stud nut is installed and tightened on the stud. The stud is then turned in its socket with an inch-pound torque wrench. The torque should range from 20 to 35 inch pounds. If reading is below the minimum, replace the joint.

To check lower joint, jack up under the frame rather than under lower control arm to maintain the coil spring load on the lower joint. Then grasp the tire at the top and bottom and move it in and out. If movement at edge of tire exceeds ⅛", ball joint is worn and should be replaced.

FRONT END REPAIRS

Figs. 8 and 9 show the front suspension on Fairlane and Meteor, respectively. Whenever any part of the front suspension has been removed and installed, front wheel alignment must be checked.

Upper Ball Joint Replace

Both the ball joint and the plate that retains the rubber seal are attached to the arm with the same rivets. Therefore, the entire ball joint assmbly will have to be removed when replacing the rubber seal.

1. Position a support between the upper arm and frame side rail as shown in Fig. 10.
2. Raise car, position safety stands and remove wheel assembly, being careful not to damage brake lines.
3. Loosen nut from upper ball joint.
4. Position tool shown in Fig. 10 so that it seats firmly against the ends of both studs.
5. Turn tool with a wrench until both studs are under tension. Then, with a hammer, tap spindle near upper stud to loosen it from spindle. *Do not loosen stud with tool pressure alone.* Remove nut and raise stud out of spindle.
6. Remove ball joint from arm. If joint is riveted to arm, do not bend arm when driving out rivets.
7. Install new ball joint, using only the special hardware contained in the kit.

Wheel Spindle Replace

1. Raise car and place support tool as shown in Fig. 10.
2. Remove wheel, drum and brake backing plate.
3. Disconnect tie rod from spindle.
4. Remove ball joints.
5. Install new spindle and complete installation in reverse order of disassembly.

Front Spring Replace

1. Raise car and remove wheel.

Fig. 9 Meteor front suspension

Fig. 11 Compressing or releasing spring in car

2. Remove suspension bumper and bracket.
3. Remove shock absorber.
4. Install one mounting bracket bolt to hold spring upper seat to spring housing while spring is being compressed, Fig. 11.
5. Position tool shown in Fig. 11.
6. Compress spring by turning tool shaft (impact wrench shown).
7. Remove bolt holding spring upper seat, then remove spring and tool from housing, Fig. 12.
8. Place spring and tool in a vise. Scribe two marks on narrow side of spring upper seat for proper alignment for replacement spring, Fig. 13. The first mark should be aligned with the center line of the caged nut. The second mark should be ¾″ from the first and in alignment with the end of the bottom coil.
9. Release spring tension by turning tool shaft and remove tool and seat from spring.
10. Reverse removal procedure to install.

Upper Arm Replace

1. Remove front spring and loosen upper ball joint stud nut 1 or 2 turns.
2. Working from engine compartment, remove upper arm inner shaft bolts, Fig. 1.
3. Remove upper ball joint and upper arm.
4. Reverse removal procedure to install the arm, being sure that the bolts and caged nuts are centered as shown in Fig. 14.

Shock Absorber Replace

1. Raise car and install safety stands.
2. Remove lower retaining nuts.
3. Remove upper mounting bracket retaining nuts.
4. Move mounting bracket-to-dash panel brace to one side. Then remove bracket and shock absorber as a unit.

Fig. 10 Loosening upper ball joint stud in spindle. Note location of arm support

Fig. 12 Removing or installing spring in car

Fig. 13 Removing or installing tool and upper spring seat

Fig. 14 Shaft centered in upper suspension arm

HORN SOUNDER & STEERING WHEEL

The horn button or ring can be removed by pressing down evenly and turning button counterclockwise until it lifts out.

Mark steering shaft and wheel hub before removing wheel so that the relationship between the wheel and steering gear is maintained when reinstalled. Then remove the nut from the steering shaft and use a puller to remove the wheel.

STEERING GEAR

Adjustments

1. Disconnect pitman arm from steering arm-to-idler arm rod. With power steering, disconnect arm from control valve ball stud.
2. Loosen sector adjusting screw lock nut, Fig. 15, and turn adjusting screw counterclockwise.
3. Measure worm bearing preload by attaching an inch-pound torque wrench to the steering wheel nut.
4. With steering wheel and sector gear off center, read pull required to keep wheel moving for at least one-half turn. If torque or preload is not within 4 to 7 inch pounds (2 to 4 with power steering), adjust as follows:
5. Loosen steering shaft bearing adjuster lock nut and tighten or back off bearing adjuster to bring preload within specified limits. Tighten lock nut and recheck preload.
6. Turn steering wheel slowly to each stop. Then rotate wheel back one-half of the total travel to center the steering gear.
7. Turn sector adjusting screw clockwise until a pull of 9 to 14 inch pounds (5 to 9 with power steering) is necessary to rotate the gear past its center position. No perceptible backlash is permitted at 30° position on either side of center (1 and 11 o'clock positions).
8. Tighten sector adjusting screw lock nut and recheck backlash adjustment.
9. Connect pitman arm to steering linkage.

Steering Gear Replace

1. Raise car and install safety stands.
2. With power steering, remove power cylinder mounting bracket from underbody.
3. Remove pitman arm from steering gear.
4. Remove gear housing attaching bolts.
5. Remove flexible joint clamp bolts and remove gear from car.
6. Reverse removal procedure to install gear.

Steering Gear Repairs

1. Rotate steering worm until nut is in center of travel, Fig. 16.
2. Remove sector shaft nut, Fig. 16.
3. Use puller to remove pitman arm.
4. Remove side cover screws and remove side cover and sector shaft from housing.
5. To remove side cover from sector shaft, turn adjuster screw in end of sector shaft down through cover.
6. Remove screws and take out end cover with worm bearing, outer race and thrust washer.
7. To remove lower worm bearing, outer race and thrust washer from

Fig. 15 Steering gear adjustments

Fig. 16 Steering gear disassembled

cover, loosen worm bearing adjuster screw lock nut and turn screw in through cover.

8. Grasp lower end of steering worm and draw steering shaft and nut out of steering housing. *Be sure to keep shaft in horizontal position so that nut does not move against stops at any time, causing damage to ball return mechanism.* Disassembly of worm nut is not recommended.

Assemble

1. Install worm shaft and nut assembly in gear housing, keeping ball nut away from stops on worm.
2. Install worm bearing adjusting screw with lower worm bearing, outer race and thrust washer in end cover.
3. Install end cover and attaching parts on gear housing, making sure bearings seat properly.
4. Tighten worm bearing adjusting screw until a slight drag is felt on bearings. Do not tighten lock nut.
5. Install pitman arm.
6. Install sector shaft and adjusting screw inside cover.
7. Rotate steering column until ball nut is in center of travel so that center tooth on sector shaft will enter center space on nut.
8. Install side cover and sector shaft in gear housing.
9. Tighten sector shaft adjusting screw until a slight drag is felt on bearing but do not tighten lock nut.
10. After steering gear is installed in car, adjust as outlined previously.

POWER STEERING

Pump Removal

1. With suction gun remove as much fluid as possible from reservoir.
2. Disconnect and fasten two hose at pump to a raised position to prevent fluid from draining out.
3. Remove pump belt. Unfasten and remove pump.
4. Figs. 17 and 18 illustrate pump components. Use all parts of the kit when overhauling the pump.
5. Installation is made in the reverse order of removal. Fill the reservoir to the "F" mark on the dipstick. Run the engine and turn the steering wheel several times from one extreme to the other. Then check for leaks.

Control Valve Removal

1. Disconnect fluid fittings at control valve and drain fluid from lines by turning wheels to left and right several times.
2. Loosen clamp at right-hand end of sleeve. Remove roll pin from steering arm-to-idler arm rod through slot in sleeve.
3. Remove ball stud from sector shaft.
4. Turn wheels fully to left and unthread control valve from idler arm rod.

Service Notes

1. When disassembling control valve, refer to Fig. 19. When reassembling, observe the following:

Fig. 17 Power steering pump housing, carrier and shaft

Fig. 18 Power steering pump cover components

Fig. 19 Power steering control valve and sleeve assembly

Fig. 20 Power steering cylinder

2. During assembly, coat all parts with automatic transmission fluid.
3. Make sure lube fitting is turned on tightly and does not bind on ball stud socket.
4. Rotate spool while inserting it in housing. Do not nick or scratch spool during installation.
5. When installing the centering spring, compress the spring and install nut on bolt. After tightening nut securely, loosen it not more than ¼ turn. Excessive tightening of nut may break stop pin at the travel regulator stop.
6. Move ball stud back and forth in sleeve slot to check for freedom of movement. Apply silicone grease to sealing areas.
7. When installed on car, measure distance between center of lube plug in the sleeve and center of the stud at the inner end of the left-hand spindle connecting rod. This distance should be $4\frac{3}{16}$". If not correct, disconnect ball stud from sector shaft arm and turn valve on idler arm rod to increase or decrease the distance. When distance is correct, align hole in idler arm rod with slot near end of valve sleeve. Install roll pin in rod hole to lock valve in position on rod.
8. After installation is completed, run engine for about two minutes to warm the fluid in the system. Turn steering wheel from one extreme to the other several times and check the system for fluid leaks.
9. With engine running, check position of steering wheel when front wheels are in straight-ahead position. Do not make any adjustments until toe-in is checked. Then adjust toe-in if necessary and center steering wheel as outlined under *Toe-In Adjust.*
10. Hook a spring scale to the rim of the steering wheel and measure the pull required to turn the wheel in both directions with the engine running. The pull should not exceed 4½ pounds and should be about equal in both directions.

Power Cylinder

1. To remove power cylinder, Fig. 20, remove two fluid lines from between control valve and power cylinder. Move front wheels to left and right several times to drain fluid from power cylinder.
2. Remove nut from outer end of piston rod. Do not remove from idler arm bracket at this time.
3. Remove locknut that holds cylinder on mounting stud in idler arm rod. Then pull piston rod out of bracket and remove cylinder from stud.
4. Remove boot, inner bushing and washer from stud and pull inner insulator and washer from piston rod.
5. Reverse removal procedure to install the cylinder. When installed, run engine for two minutes to warm up the fluid. Then turn wheels to left and right several times and check for leaks. Refill fluid reservoir to "F" mark on dipstick.

Instruments, Radio and Windshield Wiper

INSTRUMENTS

To replace the fuel gauge, temperature gauge, speedometer and cluster dial, it is necessary to remove the instrument cluster assembly.

1. Disconnect battery cable and cable at speedometer head. Remove instrument cluster wiring harness from two clips at rear of cluster.
2. Remove cluster retaining screws from instrument panel. Pull out cluster and place it on steering column. Protect column with cloth.
3. Disconnect fuel and temperature gauge wires, turn signal flasher and constant voltage regulator.
4. Remove lights from cluster.
5. Remove cluster assembly.
6. Remove screws attaching cluster to bezel and remove bezel. Instruments may then be removed.

RADIO REPLACE

1. Pull off control knobs and remove nuts retaining radio to instrument panel.
2. Disconnect antenna lead to right side of radio, speaker lead and pilot light wire at wiring harness.
3. Disconnect radio lead wire at fuse panel and remove wire from clips.
4. Remove radio back support bracket-to-radio retaining nut.
5. Remove radio from instrument panel.

WINDSHIELD WIPER

1. Disconnect wiper links drive arm from wiper motor drive shaft (under instrument panel).
2. Disconnect wires from motor.
3. Remove motor mounting bolts and remove motor.
